Dr. Dekker maintains that, owing to the impermeability of the superficial layers of the skin, inunction with preparations of tuberculin and dead bacilli has uncertain effect, except in the form of Moro's keratolytic ointment. Scarification, however, offers a much more effective method of introducing therapeutic agents to deeper layers of the skin, and promoting changes which enable the skin to produce its beneficial effects on disease. As an example of immunizing results produced in this way, Dr. Dekker quotes the experiments on anthrax carried out by Besredka in guinea-pigs. It was only by scarification of the skin, or by intracutaneous injection, that these animals could be rendered immune to the disease. Inspired by these experiments, and by researches conducted by Verploegh which showed the relative dangers of different methods of introducing tuberculin into the organism, Dr. Dekker came to the conclusion that for the tubercle bacillus, as for anthrax, the staphylococcus, and the streptococcus, it is in the deeper layers of the skin that immunizing bodies are chiefly elaborated. When the skin is scarified, and tuberculin rubbed in, some of the vaccine penetrates into the blood or lymph streams, and a focal reaction is produced. But at the same moment the endothelio-reticular layer has been activated; defensive elements are poured into the blood, and bacilli and toxins which have escaped from the focus of disease are destroyed. With repeated supplies of defensive elements, kept up by a series of cuti-vaccinations, the foci are themselves attacked, and the disease may become fully checked. It is only, says Dr. Dekker, when the production of antibodies by the skin has become insufficient to strangle the morbid processes at the centres of infection that the process of cuti-vaccination is contraindicated. Such conditions, he thinks, are only met with in very advanced stages of the disease, when common prudence suggests interfering with the patient as little as possible. In such cases prolonged intoxication prevents the formation by the skin of sufficient antibodies. Whatever may be thought of Dr. Dekker's theories, it is at least interesting that tuberculin, notwithstanding its condemnation as a therapeutic agent by a congress in London in 1913, is still thought worthy abroad of observation as to its effects, and of the building up of hypotheses to account for its action.

HELMINTHOLOGY.

THE study of the parasitic worms has of recent years become more and more important, and a large, if scattered, literature has grown up round the subject. Accordingly, Dr. BAYLIS's new *Manual of Helminthology*[5] is opportune. The task which he has set himself is a difficult one, and to include within the compass of some three hundred pages short, yet concise, descriptions of all the helminthic parasites of man and the domestic animals, calls for no inconsiderable powers of compression. The descriptions are necessarily brief, but are lucid and sufficient. The essential facts of those life-histories which are known are sketched in outline only; and as the scope of the book is confessedly biological, little or no reference is made to pathological, clinical, or therapeutical aspects of helminthology. Accordingly, the full title "A Manual of Helminthology: Medical and Veterinary" is somewhat misleading. As a textbook for classes of medical men studying parasitology, it has definite limitations, since the human parasites constitute a comparatively small portion of the whole, and the biology is not considered in sufficient detail to suit their needs. As a reference book for laboratory workers who take a wider view of their subject, or for workers in the tropics who are interested in the parasites which they may encounter in the domestic animals and birds, it should prove invaluable.

The manual falls into two parts, dealing with the flat and round worms respectively; these in turn are subdivided into flukes and tapeworms, nematodes, and thorny-headed worms; and each part is preceded by a general account of the group. Within the groups the parasites are considered systematically without reference to hosts. At the end of the book is a set of host indices showing the parasites of man and the principal domestic animals, arranged under the names of the hosts, together with a comprehensive general index. The volume is well and generously illustrated and strongly bound, and the author is to be congratulated on having produced, within the limits set by its conception, a thoroughly useful and readable manual.

POST-OPERATIVE PHLEBITIS.

PROFESSOR DUCUING has written a full and interesting account of post-operative phlebitis, thrombosis, and embolism[6] that can be confidently recommended to surgeons as the latest word on a subject of no little importance. The author begins with chapters on the histology, etiology, pathology, and symptoms of post-operative phlebitis in its various clinical forms. He has seen 225 cases of phlebitis occur in his last 3,000 operations, including all the forms of phlebitis, mild and severe, that were identified; this relatively high percentage of cases, much higher than the percentages recorded by other surgeons, is naturally to be attributed to the greater care with which evidences of phlebitis have been sought for in this series. Similarly, with embolism, Professor Ducuing enumerates 300 instances in 3,000 operations, while other writers have recorded no more than from 2 to 7 cases per 1,000 operations. Elaborate chapters discuss the sequels, diagnosis, prognosis, pathogeny, and treatment of such thromboses and embolisms, over 100 pages being given to those unsatisfactory matters, their prophylaxis and treatment. Full details of preoperative prophylactic vaccination and of treatment by anticoagulating substances are set down, and also the author's own unsatisfactory trials of leeches and leech extracts in the treatment of established post-operative phlebitis. When all is said and done, these operative risks—thrombosis and embolism—remain impossible to foresee and well-nigh intractable. The book is well arranged and well written; it contains an immense amount of valuable information, and should be of great service to all medical men who are interested in the subject with which it deals.

NOTES ON BOOKS.

THE appearance of the third edition of *The Treatment of Fractures and Dislocations in General Practice*[7] is good evidence that Messrs. MAX PAGE and ROWLEY BRISTOW's work is appreciated by the medical public. The book has been kept up to date and improved by the addition of a number of line drawings which bring out the important features of radiographs. Some sections have been rewritten. This edition may be commended as a practical guide to the up-to-date treatment of fractures.

[5] *A Manual of Helminthology: Medical and Veterinary.* By H. A. Baylis, D.Sc. London: Bailliere, Tindall and Cox. 1929. (6½ × 9½, pp. xi + 303; 203 figures. 30s. net.)

[6] *Phlébites, Thromboses et Embolies Post-opératoires.* Par J. Ducuing. Préface du Professeur J.-L. Faure. Paris: Masson et Cie. 1929. (6½ × 10, pp. xxxii + 512; 65 figures, 16 charts. 60 fr.)

[7] *The Treatment of Fractures and Dislocations in General Practice.* By C. Max Page, D.S.O., M.S., F.R.C.S., and W. Rowley Bristow, M.B., B.S., F.R.C.S. Third edition. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (Demy 8vo, pp. xvii + 284; 161 figures. 14s. net.)

Chronic rheumatism is one of the most widespread complaints in Great Britain, and it is therefore of considerable interest to read how it is regarded in other countries. Drs. WEISSENBACH of Paris and FRANÇON of Aix-les-Bains have made a very thorough study of the subject, and their book on the causes and treatment of chronic rheumatism[8] gives a lucid and complete picture of the way in which it is approached in France. The first part of the volume deals with the etiology and pathology of chronic rheumatism; and here the authors discuss the notion of focal infection that is so widely accepted in this country and in America as a common cause of the disease, and dismiss it as unproven but still worthy of further investigation. They find more trustworthy evidence of the pathogenetic causes of chronic rheumatism in factors such as toxic and humoral disturbances, and troubles involving the vascular or nervous systems, the ductless glands, and, finally, in the arthritic diathesis—though their discussion of "arthritism," one of the blessed words of French medicine, shows that they do not accept all that is claimed for it in the pathogenesis of chronic disorders of the joints. The second and third parts of the volume deal with the diagnosis, prophylaxis, and treatment of chronic rheumatism, particular attention being paid to hydrotherapy and spa treatment; nothing seems to be said about vaccine treatment. The book is well arranged, and is clearly the work of medical men with open minds and considerable experience; it may be warmly recommended to medical readers in search of an authoritative account of the subject with which it deals.

We have received a collection of papers delivered at the tenth post-graduate course held at Karlsbad in 1928,[9] and, although it purports to be directed specially to the subjects of balneology and balneotherapy, only a few of the papers have a bearing on this subject. Others are concerned with metabolic questions, endocrine physiology, and surgical subjects such as chronic suppurative middle-ear disease, while Professor MacLean contributes a paper on the alkaline treatment of gastric and duodenal ulcer. The contributors are authoritative, and the papers attractively presented and adequately illustrated. At the beginning of the book there is a collection of portraits of all those who have contributed to the first ten courses.

Professor WILSON'S *Laboratory Manual of Physiological Chemistry*[10] is a revision of one written by Professors Jones and Wilson and used for several years at the Johns Hopkins University and the University of Pennsylvania. The first hundred pages deal with the general outlines and processes of physiological chemistry, while the rest of the volume is devoted to the various tissues and fluids of the body. The text is found only on the left-hand page when the book is opened, the right-hand pages being blank for the reception of the user's notes. The book is concisely and clearly written, and may be warmly recommended to senior students with a good working knowledge of chemistry and physics. One cannot help thinking that it would be improved by the addition of an index.

To the second edition of her little book on *The Hygiene of Marriage*[11] Dr. EMSLIE HUTTON has added chapters on menstruation and the menopause, and on sterility. It is curious to reflect that civilization should have led in man to the necessity for instruction in such a natural instinctive act as consummation of marriage. However, Dr. Hutton, in common with most medical practitioners, is convinced that much unhappiness, and even ill health, is caused in some married people by ignorance of the facts of sex. The average healthy couple will probably get on quite comfortably without her book. Those in difficulty will find reassurance from its perusal. As we said of the first edition, the language is quiet, but explicit, the taste and tone are unexceptionable, and the information is generally in accordance with scientific knowledge.

The book on *Soap Films*[12] by Mr. A. S. C. LAWRENCE gives an interesting and scientific account of a subject that was, no doubt, of great attraction to us all in the nursery, and has yet been employed by physicists to afford information of critical importance in the physics of the molecule and the atom. Soap films have engaged the attention and pen of many men of science, from Plateau in the earlier days to Vernon Boys, Dewar, and Perrin in the later. Mr. Lawrence's book deals in a practical and scientific spirit with the whole subject of the production of soap films and with the interpretation of the various optical phenomena they present. It should appeal to chemists and physicists in the first instance, but may be warmly recommended to the attention of all general readers interested in the subject and willing to take a little trouble over the mathematical and chemical formulas involved in the author's clear and well-written exposition. The book is well illustrated and well produced.

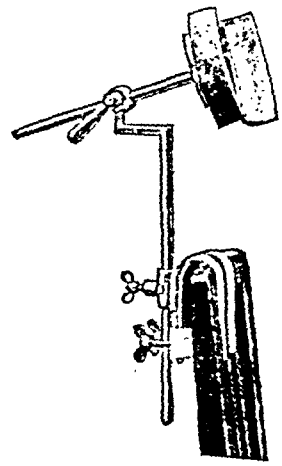
PREPARATIONS AND APPLIANCES.

HEAD REST FOR USE IN NOSE AND THROAT WORK.

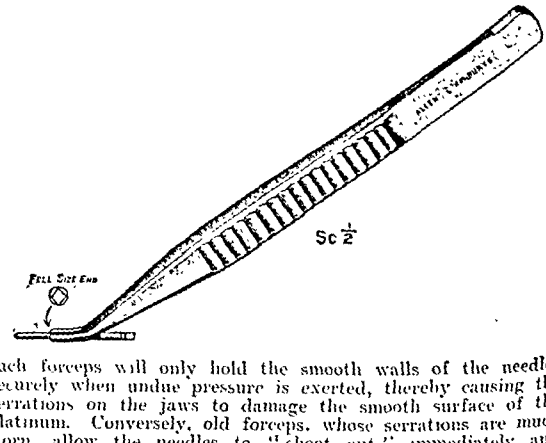
DR. L. J. CURTIN (*oto-laryngologist, Royal Victoria Eye and Ear Hospital, Dublin*) writes: Very often when performing minor operations on the nose and throat away from the operating theatre or consulting room one feels the need of



a head rest for the patient. The illustration shows such a head rest, made to my design by Messrs. Mayer and Phelps (New Cavendish Street, W.). It is portable, light, and in a few moments readily adjustable to any type of chair, while at the same time it gives the necessary support to the patient.

FORCEPS FOR RADIUM NEEDLES.

DR. F. E. CHESTER-WILLIAMS (*medical officer in charge of the Radium Therapy Department, Royal Infirmary, Bradford*) writes: The constant handling of radium needles, particularly in the "making-up" room where they are threaded or placed on the surface of Columbia paste collars, is associated with definite dangers to the workers. To minimize these risks as far as possible, all needles are held with forceps, the ordinary long dissecting forceps being most commonly used. The jaws of



such forceps will only hold the smooth walls of the needles securely when undue pressure is exerted, thereby causing the serrations on the jaws to damage the smooth surface of the platinum. Conversely, old forceps, whose serrations are much worn, allow the needles to "shoot out" immediately any pressure is applied to them, with the result that the needles may be difficult to recover, or even lost altogether.

I have had made for me by Messrs. Allen and Hanburys, Ltd., the forceps illustrated herewith. They are shaped like the well-known Childe's dissecting forceps, but, having angular cut jaws, they readily adjust themselves to, and firmly hold without undue pressure, any needle from 1.75 mm. diameter to 2.2 mm. diameter.

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE nineteenth annual meeting of the Oxford Ophthalmological Congress was held at Oxford on July 4th, 5th, and 6th. Members met informally at dinner on July 3rd in the Hall of Keble College, which had again offered its hospitality as in former years. The attendance of 112 constituted a "record" in the history of the Congress, and the present one was generally regarded as the most successful that had been held. The advantage gained by the all-too-short stay in the College, where each member is assigned rooms and becomes for the time being a student again, is a prominent feature of this successful annual gathering of ophthalmic surgeons, which was founded by the late Robert Doyne nearly twenty years ago. The proceedings of the Congress were held in the department of human anatomy of the University, kindly lent for the purpose by Professor Arthur Thomson. In addition to the scientific exhibitions, fourteen well-known firms of ophthalmic instrument makers showed the latest forms of apparatus and instruments.

The new Master this year was Mr. Bernard Cridland, who has been secretary for the past sixteen years. This appointment has been received with high approval by the members, as it is common knowledge amongst them that one of the great factors in the continuous success of the Congress had been the yeoman work put into the organization and arrangements of the meetings by Mr. Cridland.

An unusually large number of foreign members, and others resident abroad, attended the Congress this year, among whom were Professor Josef Meller of Vienna, Professor Lundsgaard and Drs. Holgar Ehlers (Copenhagen), Holland (Quetta), Bernard Samuels (New York), Thomas Poole (Washington), Swan (Evaston), Lichtenberg (Kansas City), and J. A. van Heuven (Utrecht).

Treatment of Diseases of the Lacrymal Sac.

The proceedings commenced on the morning of July 4th with a short address of welcome by the MASTER. Immediately following this, Professor MELLER opened his address with a short historical summary of the treatment of diseases of the lacrymal sac, pointing out that the idea of making an opening into the nose could be traced back to Celsus. In the eighteenth century Woolhouse suggested the purely surgical operation of extirpation of the sac, and, finally, Professor Meller brought the historical review up to the methods of Toti and West in the present century. Contemporary methods of treatment were then discussed for pure epiphora without ascertainable involvement of the lacrymal passage. From this Professor Meller passed on to the treatment of pure stenoses, and considered those cases which would be benefited by probing. The great value of employing x rays before treatment was insisted upon, and the use of thick probes deprecated. Strictorotomy of the duct was next described. The medicamental treatment of chronic dacryocystitis was then fully explained. Following this, the treatment of acute purulent dacryocystitis was illustrated, and the operative treatment of chronic dacryocystitis was delineated. The technique of the operation of extirpation of the sac was minutely described and the difficulties were emphasized. The various intranasal operations were related and commented upon.

Professor Meller's address was listened to with rapt attention by his large audience, and was a triumph of lucid expression in faultless English; at its conclusion he was accorded quite an ovation.

Dr. J. S. FRASER approached the lacrymal question from the rhinological standpoint. He confined his attention to the results of 103 dacryocystostomy operations, describing the technique minutely, its difficulties, complications, and results.

The papers were discussed by Mr. HARRISON BUTLER and by Mr. EDWARD D. D. DAVIS, who mentioned the nasal causes of dacryocystitis, of which in a series of ten cases lupus had caused five, atrophic rhinitis one, enlarged cystic middle turbinate three, and carcinoma of the ethmoid one. Mr. Davis stated that his experience of West's operation had not been satisfactory. He emphasized the value of lipiodol in x-ray photographs as a means of diagnosis. Mr. BROWNING, Mr. JAMESON EVANS, and Professor LUNDSGAARD also joined in the discussion, the last-named raising the question of tuberculous lacrymal disease, and pointing out that it was generally secondary to a nasal infection. He drew attention to the Finsen light, mentioning that it had no perceptible effect on the closed sac, but was decidedly favourable when the cavity was open. Professor MELLER replied to the discussion.

Vascularization of the Vertebrate Eye.

The Doyne Memorial Lecture, the most important contribution to the proceedings of the Congress, was delivered on the morning of July 5th by Miss IDA MANN, D.Sc., F.R.C.S., the title being "Some observations on the vascularization of the vertebrate eye."

Prefacing her remarks with a fitting tribute to the founder, the late Robert Walter Doyne, the lecturer, for the purpose of this study, classified the intraocular vessels into three groups, those of the retina, iris, and choroid. The choroid was only briefly described, emphasis being laid on the vessels of the retina and iris. Miss Mann commented on the stability of the structure of the choroid throughout the phylum, and mentioned certain modifications which appeared in some fish, producing the structure known as the choroidal gland. Reference was also made to the reflecting membranes—the argentea in fish and the tapetum of the carnivora. It was pointed out that the variations of the retinal and iris vessels were of great interest, as would have been expected, because both sets appeared relatively late in ontogeny in all species. The development of the hyaloid vessel was minutely described and the varying forms were noted; it was only in the higher mammals that a single vessel was found.

The main varieties of the adult retinal blood supply which were found among vertebrates were: (1) a completely avascular retina, the blood supply being entirely from the choroid; (2) an avascular retina associated with a pecten; (3) a vascular retina supplied by vessels lying on its inner surface; and (4) a vascular retina supplied by vessels ramifying in its substance. The modifications of the anterior end of the hyaloid vessel were divided into two groups, those with and those without a pupillary membrane during development. The former were confined to the mammals, while the latter were found in the rest of the vertebrates.

The lecture was illustrated by over sixty lantern slides, which were of very great interest. These were chiefly drawn under slit-lamp illumination at the Zoological Gardens in London, and comprised among them anterior ocular drawings of a salamander, a python, and numerous fish. The lecture was delivered in a very clear and lucid manner, and commanded the greatest attention. At its conclusion Miss Mann was presented with the Doyne Memorial Medal for the year.

Ocular Manifestations in Head Injuries.

Mr. HUGH CAIRNS opened a discussion on the ocular manifestations found in head injuries. He thought that undue attention had been paid to the actual fracture of the skull and too little to the underlying brain. The importance of the intracranial pressure was stressed, being caused by haemorrhage or oedema of the brain substance. It was difficult to decide which cases would benefit by operation and which would not. Blurring of the optic discs was seen in many cases where there was a large blood clot in the brain. In 80 patients, only 7 showed definite papilloedema; this sign was an indication for operative measures, which would give the patient a better chance, and obviate the chronic ill health which so frequently followed head injuries. Dilatation and fixation of the pupil indicated the side of the most serious lesion. Homonomous visual field defects were rarely seen in civil practice, and injury to the fibre tracts and nuclei were also rare. Persistent headache and photopsia following a head injury were not functional, but were probably due to an unresolved cerebral contusion.

Mr. CHARLES GOULDEN, who treated the subject from the point of view of the ophthalmic surgeon, described very fully the direction which fractures took when blows were applied to certain parts of the skull. He showed that a rupture involving the optic canal could occur in any fracture of the skull, but was most common when the blow was in the neighbourhood of the external angular process. The various ocular symptoms due to haemorrhage into the sheath of the optic nerve were described, and the important pupillary reactions well portrayed. The various ocular paralyses were minutely detailed and their localizing value explained. Pulsating exophthalmos and its causation were described; consideration was also given to haemorrhages into the orbital region and dislocation of the eyeball with its mechanism.

The discussion was continued by Mr. JAMESON EVANS, Mr. RIDLEY, Mr. HARRISON BUTLER, Mr. COLLYER SUMMERS, Mr. COULTER, Mr. TRAQUAIR, Mr. NORMAN PIKE, Mr. BAMFORD, Mr. STEWART BARRIE, and Mr. DAVENPORT.

Miscellaneous Papers.

The proceedings on the morning of July 5th were opened by Dr. THOMAS POOLE of Washington, whose paper on the effects of disease of the paranasal sinuses upon the fixation point should be studied in the original. It was discussed by Mr. MADDOX and Dr. ROSA FORD.

Mr. RIDLEY then read a paper on an unusual complication of Hodgkin's disease in which the lacrymal glands were seriously infected.

Mr. NICHOLAS HUGHES contributed an original and interesting paper on the structure of the vitreous. Research had been conducted on sheep's eyes in which the vitreous was suspended in a vessel containing a solution of sodium chloride of a specific gravity adjusted to that of the vitreous. Observations were then made with the arc slit-lamp. The investigation showed that the vitreous had a slender attachment to the optic disc and a much firmer union to the ciliary processes. The interior of the vitreous was occupied by membranes which had a remarkable disposition; their structure was fully described in the paper.

In the afternoon Lieut.-Colonel H. HERBERT read a paper on the cement substance of the intraocular muscles and chronic glaucoma.

On Saturday morning Mr. BERNARD SAMUELS of New York gave a paper entitled "Necrosis of the iris," the results of his research work in the Vienna Clinic under Professor Fuchs. It was illustrated by a number of slides, which demonstrated the condition very clearly. It was discussed by Professor MELLER, who emphasized the difference between primary and secondary necrosis of the iris.

Mr. PHILIP ADAMS, the deputy master, contributed a most interesting paper on three cases of toxic amblyopia, due respectively to iodoform, digitaline, and chlorodyne. This was discussed by Dr. STEWART BARRIE, Mr. TRAQUAIR, Mr. HARRISON BUTLER, and Mr. CRAIG.

Dr. H. T. HOLLAND of Quetta then read a very instructive paper on iritis as a post-operative complication of cataract extraction, comprising a review of 2,627 consecutive extractions for cataract, of which the large majority had been intracapsular, and showing that a higher proportion of iritis ensued in those operations which were performed with capsulotomy. This was discussed by Professor MELLER, Mr. HARRISON BUTLER, Mr. TRAQUAIR, Dr. SAMUELS, Mr. CRIDLAND, and Mr. RUSS WOOD.

Demonstrations.

During the afternoon of July 4th there were demonstrations in the Scientific Museum. Mr. MADDOX showed his cheiroscope and frame-fitting method. Miss MADDOX demonstrated a few simple expedients in squint training. Mr. BURDON-COOPER exhibited spectrograms showing the composition of the ash in the senile cataractous lens. Mr. THOMSON HENDERSON demonstrated a specimen of an intradural tumour of the optic nerve. Mr. RAYNER BATTEN contributed a collection of drawings illustrating disease of the macular region. Mr. ARMSTRONG showed a recording scotometer, and Mr. GEORGE YOUNG a case of transplantation of the whole cornea and conjunctiva.

Social Events.

At the conclusion of the afternoon's proceedings, on July 4th, members and their friends repaired to the gardens of Exeter College for tea, where they were welcomed by the Vice-Principal of Ripon Hall, the Rev. J. S. Bezzant, Fellow of Exeter College, and Mrs. Bezzant, and also by Mr. Philip Adams, Fellow of Exeter College and deputy master of the Congress, who, with Mrs. Adams, kindly acted as hosts and hostesses.

The annual dinner of the Congress was held in the evening in the Hall of Keble College, at which the largest number in the history of the Congress attended. Among the guests were the Dean of the Oxford School of Medicine, Dr. Ainley Walker, the Rev. J. S. and Mrs. Bezzant, Dr. J. S. Fraser, and Professor Meller. The Master, Mr. BERNARD CRIDLAND, mentioned that 23 new members had been elected during the year, and the total membership was now 411. He regretted the loss, through death, of Drs. Andrews of California and Beauman of South Africa. The Master then gave a detailed account of the history of the Congress from the time of its inception, nineteen years previously, pointing out its remarkable and steady progress, until it had assumed its present position of importance in the ophthalmological world. After referring to the numerous foreign and overseas members who were there, he drew attention to the presence of Mr. Richardson Cross of Bristol, a member of the original council of the Congress, and added, further, that three-fourths of the members of the executive of the Congress at the present time were former pupils of Mr. Richardson Cross. The toast of "The Visitors" was proposed by the deputy master, Mr. PHILIP ADAMS, and replied to by Dr. AINLEY WALKER.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

INCIDENCE AND CONTROL OF MENTAL DEFICIENCY.

On the closing day, July 12th, of the annual meetings of the Royal Medico-Psychological Association, held at the British Medical Association House, Tavistock Square, under the presidency of Dr. NATHAN RAW, a discussion took place on the report of the Mental Deficiency Committee (the joint committee of the Board of Education and the Board of Control), which is now available in its entirety, including Part III, on the mentally defective adult.

Dr. A. F. TREDGOLD, a member of the committee, gave an outline of the report. Much confusion on the subject of mental deficiency, he said, was due to the different criteria adopted, on the one hand in the Mental Deficiency Acts, and on the other in the Education Acts. The committee had proceeded on the basis that mere lack of educational attainments could not in itself be regarded as constituting mental deficiency; the only criterion was social incapacity. In 1908 the inquiry by the Royal Commission on the Feeble-minded estimated that there were 4.6 mental defectives per 1,000 of population; Dr. E. O. Lewis in the present report gave the number as 8.56 per 1,000. The higher incidence was to some extent more apparent than real; in other words it was due to a more complete investigation, but not all the increase could be explained in that way. If it were so, one would expect to find included a relatively larger number of persons suffering from mild degrees of defect, but in fact the proportions of the different grades in the two computations were almost exactly the same. It was evident that during the last twenty years there had been some definite increase in the proportion of mental defectives to the population. One factor might be the concurrent reduction in the infantile mortality rate, another the longer life span of the population generally, a third the selective decline in the birth rate; mental defectives were the offspring of a mentally subnormal stock, and the birth rate amongst these was higher than the average for the community. For years past the nation had been breeding "from the dregs rather than from the cream." With regard to the education of the mentally defective, the special schools were quite insufficient even

for the number of defectives ascertained. During the last twenty years the education of the mentally defective, formerly optional, had been made compulsory, and no doubt something had been done under the Mental Deficiency Acts, but only the fringe of the problem had been touched. There were still thousands of mentally defective children who were receiving no proper education and training, and thousands of adults totally unemployed and under no adequate supervision. There were thousands of defectives also encumbering the mental hospitals and interfering with the proper treatment of mental disorder. The magnitude of the problem was just as great as it was twenty years ago. The recommendation of the joint committee was that the local education authority should be responsible for providing suitable education according to their needs for all children under the age of 11 who were able to attend day schools and centres; the lower grades would be notified to the mental deficiency authority, which would pay for the cost of their provision, and there should be a new educational unit of retarded children. It insisted that the existing powers for dealing with defectives—the powers of supervision and guardianship—should be made real, and that there should be also the closest possible co-operation between the authorities concerned with the mentally deficient and those concerned with the mentally disordered. With this in view there should be available the services of an expert—an officer of mental health, possessed of knowledge and experience in all branches of psychological medicine—who would be responsible for co-ordinating the various clinics and arrangements. On the social and genetic aspects of the question the committee felt that the present state of knowledge was not sufficient to enable definite conclusions to be drawn as to the preventive value of segregation and sterilization, and therefore urged the need for further definite research.

Dr. W. A. POTTS said that the recommendation of the joint committee that backward and feeble-minded children should be dealt with together by education authorities without special certification had a great deal to recommend it; but at the same time the policy of taking these children together, without any clear differentiation, would possibly emphasize the difficulty that already arose from the constant mistake of talking of well-marked defectives as borderline cases. It was now demanded that all practitioners should have some instruction in mental deficiency. In 1913 it was made a duty on the part of practitioners to certify any mental defective who required to be placed in an institution, yet no provision had been made for the instruction of medical students in the necessary diagnostic work. He did not think the problem would ever be brought near solution until the proper education of all medical practitioners in this important matter was insisted upon.

Dr. JOHN CARSWELL was satisfied that the awe with which tests of intelligence had been regarded in the past had greatly obscured the early estimation of mental defect. If instruction in mental deficiency was to be set going at all it must be by those who were teaching medical students mental diseases.

Dr. A. H. MACDONALD, chief medical officer, Dr. Barnardo's Homes, had found a diffidence among medical officers in certifying children because of the stigma attached to certification. If that stigma were removed it would be possible to get more children into the special schools.

Dr. W. F. MENZIES referred to the astonishing lack of interest shown by the press in the report of the joint committee. Mental deficiency was not "copy" for the newspapers, yet many members of the public, especially lay members of public bodies, were showing the liveliest interest in this question and asking what the medical profession was going to do. His own idea was that the numbers of mental defectives were not 8 per 1,000, but nearer 12 per 1,000. There were certain rough-and-ready rules which, in country places and among the labouring population, served fairly well to assess the incidence: in the case of juveniles, had they been able to pass the fourth standard? If not, they were likely to be mental defectives. In the case of adults, marriage being almost an economic necessity among the labouring classes, if a man in those classes was not married by the age of 30 it was likely that he was a mental defective. From a rough assessment, he felt that 12 per 1,000 was a closer approximation than that given by Dr. E. O. Lewis. In North Staffordshire country districts he had been struck by three things: the astuteness of the grandparents, the fewness of the parents, and the large number of mental defectives in the third generation. The interpretation was that the past generation had been able to make a fairly comfortable living; that with financial stringency the present generation had moved to the towns, and it was surprising how many of these people had sent back their defective children to be looked after by the grandparents and unmarried aunts. On the question of sterilization, Dr. Menzies argued that our whole population was heterozygous. There was no distinction between mental defect and an acquired mental illness; it was only a question of the stage at which the toxin acted as exciting cause on the inherent instability. He did not suppose that any body of people would object to sterilization if it was going to do any good. But if sterilization was practised it would be possible to get hold only of the gross case. Again, was it desirable to be without deficiency? Mental deficiency was evidence of a genetic variation, and where there was genetic variation there were variants from the mean in both directions. If a time came when there was no deficiency, it would be a time when there was no genius either.

Dr. J. R. LORD proposed the following resolution, which was adopted:

> That the Association, being deeply concerned with the evidence of the report of the Joint Mental Deficiency Committee of the Board of Education and the Board of Control regarding the number of mental defectives in the country, the insufficient provision for their education and training, and the inadequacy of the measures for their care, supervision, and control, strongly urges upon His Majesty's Government the necessity for action being taken without delay: (1) To provide suitable educational and training facilities for all mentally defective and mentally subnormal school children and young adults. (2) To provide sufficient boarding school and institutional accommodation for all those in need of these forms of care, and to provide adequate means for the protection, care, and supervision of those not in need of institutional care.

Another resolution urged the setting up of a Royal Commission, but to this Sir C. HUBERT BOND objected, and it was eventually agreed merely to ask for a full inquiry into the causation of mental deficiency and its relationship to other abnormal mental conditions and to social problems.

It was agreed to send the resolutions to the Prime Minister, the Minister of Health, the President of the Board of Education, and the Chairman of the Board of Control.

ANNUAL DINNER.

The annual dinner of the association was held on July 10th at the Hotel Metropole, when Dr. Nathan Raw, Lord Chancellor's Visitor, presided over a large and distinguished company. The speeches, though numerous, were brief and to the point, and between some of them there were musical interludes. After the King's health had been honoured, the toast of "The City of Westminster" was proposed by Dr. J. R. Lord, and replied to by the Mayor of Westminster, Major Vivian Rogers, who had addressed the members earlier in the day in the City Hall. The toast of "The University of London and Westminster Hospital School of Medicine" was proposed by the outgoing president of the association, Professor J. Shaw Bolton, and responded to by Sir James Purves-Stewart, senior physician to the hospital. Representatives of allied societies were welcomed by Sir Hubert Bond, medical commissioner of the Board of Control, and the response on their behalf was made by Dr. Alfred Cox, Medical Secretary of the British Medical Association. The health of "The Guests and Visitors," proposed by Professor G. M. Robertson of Edinburgh, was responded to by Dr. Fleury of Geneva, Dr. J. H. Pameijer, director of the Rotterdam Mental Hospital, Lady Barrett, dean of the London School of Medicine for Women, and Sir Arthur Robinson, secretary of the Ministry of Health. The concluding toast, that of "The Royal Medico-Psychological Association," was submitted by Lord Riddell, and the president, Dr. Nathan Raw, replied.

British Medical Journal.

SATURDAY, JULY 20TH, 1929.

THE MENTALLY DEFICIENT ADULT.

IN our review of Parts I, II, and IV of the Report of the Joint Committee of the Board of Education and the Board of Control on Mental Deficiency (April 27th, 1929, p. 775) we pressed for the immediate publication of the remaining Part III, which, against the wish of the committee itself, had been withheld. The mystery of this withholding is not disclosed by its belated publication, which has just taken place.[1] This part of the committee's report is a very important and valuable document, dealing mainly with the adult defective as Parts I and II dealt mainly with the mentally deficient child. Since, however, many of the administrative and social problems presented by mental deficiency are common both to adults and to children, much inconvenient overlapping and repetition and cross-reference is involved in the separate publication of the parts. This was entirely unnecessary, and, as the committee itself evidently wishes to emphasize, the report should be studied as a whole. The earlier publication of Part III would have enhanced its value—which should still be considerable—in connexion with the administrative schemes of local authorities under the Local Government Act, 1929.

The report now issued opens with a statement of the law as it affects the adult defective, and of the functions of local mental deficiency authorities, of Poor Law authorities, and of local authorities under the Lunacy Acts. It then describes the present arrangements for the ascertainment and care of defectives by the first-named authorities, as distinguished from the arrangements that are, or should be, made by local education authorities. Ascertainment is, of course, the duty of both; and in this connexion the extraordinarily careful, laborious, and valuable special investigations carried out by Dr. E. O. Lewis, and described in Part IV of the report, necessarily come into the picture once more. The broad findings were stated in our former article. Those relating to adults may now be more particularly referred to. The total number of adult defectives of all grades in England and Wales is estimated at 150,000—some 105,000 in urban and 45,000 in rural areas. The mean incidences are 3.2 and 5.6 per 1,000 total population respectively. Of these defectives 57 per cent. are living at home, 23 per cent. are in Poor Law institutions, 14 per cent. in mental hospitals, and only 5 per cent. in certified mental deficiency institutions. Some very interesting data as to the age distribution of adult defectives are given; it is stated also that 13 per cent. of the men and only 5 per cent. of the women are almost self-supporting, that approximately half of the defectives of all grades are partially self-supporting, and that those who contribute nothing to their own support amount to about 40 per cent. of both sexes.

The methods which the State prescribes for the care of these persons are supervision, guardianship, and institutional care. None of these methods is fully or properly functioning at the present time. The exact meaning and field of each of them requires careful consideration, and the committee makes valuable suggestions under each heading for the future allocation of responsibility and improvement in the provision for the care, training, and control of defectives. If supervision and guardianship are effectively exercised (especially if a new form of guardianship by the local authority itself is established), and if in connexion with each central institution and colony there are suitable hostels in centres where employment can be obtained, and a system of licensing of defectives from the institution, the amount of institutional provision needed will be very materially reduced. The various types of institution required are described, their methods of care and occupation indicated, and the point is made that they should not be "stagnant pools," but "flowing lakes always taking in and always sending out." The happiness of the great majority of defectives in such institutions is an encouraging feature which should be better known to the public than it is. As regards numbers, about 6,000 adults would require provision in mental hospitals, while more than 1,200 would have to be dealt with in State-provided colonies as having dangerous or violent propensities. Of the remainder, some 57,000 children and younger adults should be sent to fully equipped colonies, while the 37,000 older defectives might go to some simpler form of institution. It will be appreciated that the main body of educable defective children should in any given year be provided for by the local education authorities. The amount of institutional provision now made is, therefore, appallingly insufficient, and there is no prospect in the near future of the lack being supplied. The majority of adult defectives must for many years to come remain in the general community. Up to the present they have been left to manage for themselves, with such help as their relatives can give them, and the results have been disastrous and costly. Moreover, the tendency is for defectives to be ostracized rather than socialized. The number that can be safely cared for in the community depends on the amount of training and supervision the community is willing to provide. These are complementary factors. As the report says, "To train defectives and then to neglect their social care is simply wasteful, whilst, on the other hand, successful supervision is impossible unless the defectives are properly trained."

Part III of the report concludes with an important chapter on "Mental deficiency as a genetic and social problem," which should be read in conjunction with the chapter on "The nature of mental defect" with which Part I opens. Questions of segregation and sterilization are considered in the light of the fact that mental deficiency is intimately related in its social aspects to a number of other questions, and that "if we are to prevent the racial disaster of mental deficiency we must deal not merely with mentally defective persons, but with the whole subnormal group from which the majority of them come." If, as is evidently true in view of this established principle, nothing short of the sterilization of one-tenth of the whole population can be an effective preventive measure along such lines, the question whether systematic sterilization should be resorted to has only to be asked in order to be dismissed. The adoption of this measure in individual cases and for certain very limited purposes is, however, a matter for more careful consideration; and, as the whole question of the causation of mental deficiency and its relationship to other abnormal mental conditions and social problems is at present difficult and obscure, the demand that a Royal Commission or other suitable official committee should

[1] Report of the Mental Deficiency Committee, Part III. The Adult Defective. London: H.M. Stationery Office. 1929. 1s. 6d. net.

be appointed to make full investigation of the subject is worthy of support, always provided that such inquiry is not seized upon by reluctant authorities to refrain from making the institutional and supervising provision which the report of the Joint Committee has proved to be even more urgently needed than had before been generally realized.

A SURVEY OF IRREGULAR PRACTICE.

WE complete in to-day's *Supplement* a review of irregular practice in Europe based on an inquiry undertaken last year by the Association Professionnelle Internationale des Médecins (A.P.I.M.). The review is unfortunately incomplete through the absence of information from Spain, Portugal, Italy, and Russia. If we remark also that the result of the inquiry illustrates the limitations as well as the possibilities of investigation by questionary, we must not be taken as belittling an achievement of which Dr. Fernand Decourt may well be proud. It is not always easy from the information supplied to form a clear picture of national conditions under one head or another, simply because the national standards and points of view, as well as national methods of organization, differ so widely that the connotation of the terms used may well be different for the several Correspondents. A short and definite answer to a direct question is sometimes misleading, while a detailed and explanatory reply may be difficult to correlate with the information supplied from other quarters. In face of such difficulties Dr. Decourt, on whom has fallen the chief burden, not only of framing the original questions, but of collation, translation, and condensation of the replies, has produced a valuable report, and one which serves to emphasize certain facts and point to certain conclusions of no small interest. The report ends with a suggestion for a common programme of legislation, as to the practicability of which opinions must inevitably differ. There is no doubt room for standardized methods of dealing with newspaper advertisements and the production and distribution of secret remedies, and the knowledge that abuse in this connexion has been definitely eliminated in some countries should be a useful stimulus to legislators, but beyond this it would clearly be very difficult to go, in view of the wide differences between one European country and another in the whole system of social organization.

The first point of interest is the almost universal replacement of the old system, which recognized minor medical qualifications for limited functions, by one based on a general minimum medical qualification, and the evolution of groups of competent non-medical auxiliaries, working in a well-defined professional relationship with the doctor in an increasingly definite sphere of their own. The importance of protecting these auxiliary practitioners from unqualified opposition cannot be overestimated, and it is a matter which depends at least as much upon the attitude of the rank and file of the medical profession as upon legislative provisions, for the universal recognition of the ultimate responsibility of the doctor whenever he is associated with an auxiliary worker enables him to "cover" unqualified practice amongst auxiliaries without actual breach of the law. The outstanding feature in the whole of this development is a tendency to uniformity, which throws into relief the divergent views held as to the position of dentistry, which is regarded on the one hand as a medical specialty, on the other as a co-ordinated independent profession. Another fact worth notice is the absence of any striking difference in the comparative prevalence of unqualified practice as between the countries where medical practice is legally restricted to the qualified and those where it is, theoretically at least, free. Here again there seems to be similarity in practice if not in theory. The free countries all show an imposing list of restrictions on the activities of the unqualified. The majority of the protected countries admit an amount of uncontrolled, unqualified practice which, with few exceptions, seems to equal, if not necessarily to exceed, that found in the free countries. The general tendency in both groups seems to be towards the multiplication of restrictions, the enhancement of penalties, and increased severity in administration. Complaints of the inadequacy of the law in both groups are coupled with complaints as to laxity of administration, and although the absence of special machinery for giving effect to penal measures often renders such measures nugatory, the existence of machinery to secure their application and of voluntary organization to supplement the official does not seem invariably to attain the desired object. That such voluntary organizations should be necessary is in itself an indication of a public frame of mind conducive to the continued existence of the evil. Against such an attitude it is unlikely that the law can prevail.

It might be expected that the volume of irregular practice would be found to vary inversely with the ratio of qualified practitioners to population. This, however, is not the case. It is true that Yugoslavia traces an increase in the unqualified to an absolute deficiency in the supply of qualified practitioners, but the ratio of doctors to population in three out of the four countries which seem to be least overspread by the unqualified is definitely below the mean, and in the fourth only just above it, while the ratio in the four countries which seem to have most recourse to the services of the unqualified is in only one case below the mean. The economic factor cannot, of course, be ignored. As the Swedish Correspondent points out, the unqualified practitioner starts at an advantage, since he can dispense with a costly, as well as a protracted and arduous, period of training. In some of the countries under review it seems possible that a large amount of unqualified practice is accounted for by the relatively low charges and easy accessibility of the unqualified. At the other end of the scale freedom from ethical restrictions allows greatly enhanced profits to the irregular practitioner. It is the general, though not the universal, experience that the introduction of social legislation which places the services of qualified practitioners within the reach of large sections of the population does result in a diminution of unqualified practice, and little abuse of this particular restrictive legislation is recorded. The experience of France and Hungary seems to be exceptional in this respect, and will doubtless prove transitory. Incidentally, the analysis of forms of unqualified practice suggests that the osteopath, the chiropractor, and the naturopath have found in this country pastures sufficiently rich to stop them in their eastward migration, for they seem as yet to be relatively rare on the other side of the Channel.

On the whole, the Correspondents seem to be at one in looking to improved standards of education, both general and professional, as the most effective means of eliminating the more dangerous type of unqualified practice. With this conclusion we may agree, though experience suggests that general progress in education may in certain circumstances simply replace one type of quackery by another. It is inevitable in

periods of scientific advance that test and assimilation should lag behind discovery, and the interval gives the highly educated charlatan, lay and professional, his chance. The best means of meeting this difficulty in connexion with medicine probably lies in a deliberate effort on the part of the main body of medical practitioners to educate their own patients. The replies received from Luxembourg are significant in this connexion. Taken all round, it seems safe to say that Luxembourg occupies a remarkably favourable position with regard to unqualified practice. The Correspondent is satisfied as to the adequacy of the law on the subject and the efficiency of the administration. While recognizing the dangers attending unqualified practice he can give no local examples, for the activities of the unqualified in Luxembourg seem to be of a very minor nature. No special organization seems necessary to control abuse, and, when the rare opportunity occurs, the lay press whole-heartedly supports the restrictions placed on the unqualified, and gives adequate publicity to the penalties inflicted for breach of the law. The people of Luxembourg, states the Correspondent, are kept sufficiently informed through the prevailing habit of consulting the doctor, who, as occasion offers, enlightens them about the activities of the charlatan. "The best means of controlling quackery would seem to be popular instruction by the doctor in the ordinary course of his practice." Perhaps the final word on this subject lies with the Correspondent from Poland, who points out that, while the victims of quacks are recruited from all classes of society, even the highest (and, we may add, the most highly educated according to accepted standards), all these persons show one common defect—the absence of a critical sense, coupled with a subconscious leaning to the miraculous. "To diminish the scourge of charlatanism it is necessary from the earliest years to develop a critical sense in every individual and to develop the humane outlook amongst medical practitioners, reminding them always that their patients are compact of spirit as well as body. Nevertheless charlatanism will never disappear, for there will always be persons with the congenital defect of the absence of a critical sense, a deficiency which no system of education can eradicate. These will always frequent the quack in spite of the strictest penal measures."

THE R.I.B.A. REPORT ON DAMP HOUSES.

THE report of the Royal Institute of British Architects on damp houses, to which we give prominence at page 114, is assured of a cordial welcome from the medical profession. To the British Medical Association this report is of particular interest, for it owes its origin to certain action taken by the Association's Committee on Rheumatic Heart Disease in Children. This committee, it will be remembered, in investigating the environmental factors significant in the causation of juvenile rheumatism, concluded that important among them was residence in damp dwellings; it therefore approached the R.I.B.A. with a view to discovering if expert opinion was satisfied with the conditions under which the erection of houses was proceeding. So cordially were these inquiries received that the committee was asked to attend a special meeting of the Institute, at which, following the reading of a medical paper by Dr. Reginald Miller and an architectural exposition by Mr. J. Ernest Franck, members of the two professions discussed the whole subject of damp houses. As an outcome of this meeting and of other conversations the R.I.B.A. appointed a strong subcommittee "to investigate the causes and prevention of dampness in dwellings," and it is the report of this subcommittee, approved by the council of the Institute, which has now been issued.

The report is based upon the answers received to a questionary drawn up by the subcommittee, and circularized to all members of the Society of Medical Officers of Health. It consists of an analysis of the causes of damp in over a thousand damp houses, of which 1,014 were more than ten years old and 53 less than that age. Official critics will doubtless emphasize the smallness of the number of post-war houses reported on, but those who retain their knowledge of human nature will realize that large numbers of recently erected houses are not likely to be reported as damp through official sources alone. Of the older houses exhibiting damp, 65 per cent. were damp owing to lack of maintenance, but excluding these the chief causes of damp were defective or absent damp courses and porosity of walls. Of greater moment, perhaps, is the fact that the same two faults are the commonest causes of damp in the post-war houses examined. The conclusion is therefore inevitable that the great enemy is thoroughly bad building.

There are several points on which the public needs enlightenment. Probably few are aware that a qualified architect is concerned in the building of only about 13 per cent. of the residential houses erected; that is to say, the great majority of dwellings are neither planned nor built nor surveyed by those whose profession it is to know how a healthy house should be built. Many, again, imagine that the by-laws and regulations under which residential houses are erected provide safeguards against damp. But expert architectural opinion is to the effect that this view is unduly optimistic—indeed, that with certain sites and exposures houses complying with every official by-law may be persistently damp. During the housing shortage of the last few years local authorities have been permitted to relax some of the regulations under which the erection of dwellings had hitherto been controlled, and we imagine that it will be a shock to many to realize that even now houses are being built without efficient damp courses, or, indeed, without damp courses of any kind. On this point the report is quite clear: "The high proportion of reported cases of dampness due to the absence of, or defects in, damp courses in new dwellings is surprising. While the absence of this protection in old buildings may be expected, it may be recorded that as regards buildings erected within recent years, all codes of building by-laws, and the conditions on which certain relaxations of by-laws have been permitted, are alike in calling for an adequate damp course, consequently its absence in new buildings must imply failure to comply with this by-law, while defects arise from improper compliance or the use of damp-course materials of inferior quality." Such a statement makes unpalatable reading, and it is a disagreeable thought that even such regulations as exist can be evaded through faulty supervision. The report urges that, since the by-laws as they at present stand do not provide a complete safeguard against damp, suitable amendments in the Public Health Act are necessary and should be made. When we remember how irksome are public regulations to any body of professional men striving to do their work honestly and well, this public-spirited recommendation must be taken as an index of the degree of dissatisfaction felt by architects in the present state of affairs. The alternative would seem to be simply to rest on what we believe is, strange as it may seem, still the law of the land—namely, that a dwelling-house must not be damp.

In welcoming this valuable report, which indicates so clearly the unsatisfactory state of present building operations, we may express the hope that the architectural and the medical professions, having come together to such good purpose, may not again drift apart. The combined meeting which we have already mentioned constituted, we believe, the first occasion on which the R.I.B.A. has ever been addressed by practising physicians. We hope that it will not be the last, for there are many problems of house construction, such as those appertaining to heating, lighting, noise prevention, and labour saving, to name but a few, in which co-operation between the two professions might lead to a better state of things for the public health.

THE EPIDEMIOLOGY OF MEASLES.

In the eighties of the last century most epidemiologists accepted the simple formula of Hirsch that the recurrence of epidemics of measles depended "solely on two factors, the time of importation of the morbid poison, and the number of persons susceptible to it." Some twenty years later Sir William Hamer attempted to explain the phenomena in terms of variation of the proportion of susceptibles, and Mr. H. E. Soper has quite recently[1] provided an elegant mathematical expression of the consequences of that hypothesis. Subsequent research and speculation have led to the factor of variation in susceptibility of a population being less regarded in this case, while, contemporaneously, work on other diseases—notably cerebro-spinal meningitis, poliomyelitis, and diphtheria—has had a different result. In some instances, indeed, it has appeared that variations of susceptibility, to be measured in terms other than those of clinical manifestation of "illness," should be deemed the most important objects of epidemiological study. In the memoir under notice Dr. Percy Stocks has taken variations of susceptibility not as the only, but as an important, object of his research.[2] Dr. Stocks has had at his disposal Dr. Sowden's data of measles in the metropolitan borough of St. Pancras, where measles is compulsorily notifiable. In the first part of the memoir an estimate is prepared of the numbers of children at risk both in the houses wherein, during the period of study, at least one case of measles occurred, and in the residual population. A result of this study is to show that the periodicity of epidemics cannot be satisfactorily accounted for by variations in the numbers of susceptibles, *if we assume that all children who have not had measles are equally susceptible.* Dr. Stocks then asks himself whether a temporary latent immunization might not be produced by exposure not leading to clinical manifestation. From a careful study of the histories of members of families exposed a second time to measles, he deduces evidence that such exposure has an immunizing effect which wears off gradually. The estimated rate of loss of this immunity (the method of estimation is, of course, tentative) is consistent with a roughly biennial periodicity of epidemics. Dr. Stocks next presents a study of the spatial distribution of measles, which again is consistent with the hypothesis that latent immunization is an important factor. Dr. Stocks then passes to a discussion of the term infectivity, which, as he notes, has been used in different senses by different writers. His idea is to take as an essential element of the measure of infectivity the ratio of cases occurring in an exposed group at an interval, equal to the mean incubation period, from the date of the primary case. The idea is carefully elaborated, and resultant indices of infectiousness are computed for various periods. The relation of these to meteorological conditions is studied, with results which are suggestive but not very definite. The outcome of the research may be stated in Dr. Stocks's words: "A satisfactory explanation of most of the epidemiological phenomena of measles is thus provided by the concept of an active *plus* latent immunization of the child population on the one hand, and changes in facility of transmission of the virus by droplet infection from cases or carriers to other persons coming in contact with them on the other. If we suppose that this facility can be suddenly increased two- or three-fold by favourable combinations of seasonal and atmospheric conditions, most of the phenomena can be explained without recourse to such vague generalizations as 'biological modifications' of the virus, though a few, such as certain cyclical changes in the seasonal incidence of measles epidemics, still remain unsolved." Although we are not satisfied that the rather cavalier dismissal of the late Dr. John Brownlee's conclusions, implied in one of the sentences just quoted, is justifiable—unless there is some methodological fallacy underlying Brownlee's use of the periodogram it is hard to see how the periodicities constant for a particular place and series of years, but different in different places and epochs, can be described by Dr. Stocks's hypotheses—we have no doubt that this memoir is an important contribution to epidemiological science, reflecting much credit upon its author and worthy of the great school of which he is a distinguished member. We might add that, although the memoir needs to be read with attention—for its subject is intricate—the medical epidemiologist is not called upon to grapple with abstruse algebraical formulae. In other words, there is no reasonable excuse for not reading a valuable paper.

VICTOR HORSLEY MEMORIAL LECTURE.

To a very large audience, over which Sir John Rose Bradford presided and which included Lady Horsley, Sir Thomas Lewis delivered, on July 16th, at University College Hospital Medical School, the third Victor Horsley Memorial Lecture. He prefaced his remarks with a brief tribute to the man to whose memory the lecture was dedicated. He spoke of his brilliant intellect and fascinating personality, and of the fact that to all who worked with him or for him he was a constant inspiration. Horsley was possessed of rare genius, untiring energy, and a resolute courage in his unflinching pursuit of truth. He was in the front rank of those men who, by the originality of their work, established the great tradition of the University College Hospital School of Medicine. The lecturer added that it was Horsley's fame which brought him (Sir Thomas Lewis) to that hospital, and it was in Horsley's laboratory at the college that he found encouragement to pursue his own investigational work. He was proud to have the opportunity of bringing forward some new observations in the form of a tribute to his old chief.

Sir Thomas Lewis then described some observations relating to the mechanism of Raynaud's disease which he had been carrying out recently in association with Professor William Kerr. It was Raynaud's thesis that obstruction occurred spasmodically mainly in the smaller arteries of the digits, and, further, that this spasmodic condition of the arterioles was brought about through an overaction of the vasomotor nerves. So far as the spasmodic character of the malady was concerned, Sir Thomas Lewis thought that Raynaud produced a very striking case in favour of his thesis. As for the involvement, in the main, of the small arteries of the part, Raynaud was unquestionably right, but his evidence was not very strong, and could now be strengthened. But so far as concerned the third part of his thesis—that the malady was due primarily to overaction of the vasomotor system, Sir Thomas Lewis considered that Raynaud was wrong, and that the cause was to

be found elsewhere. Raynaud's disease might be defined as Raynaud himself defined it, or (not quite the same thing) in the sense in which the term was used to-day; but neither definition would serve a very useful purpose, and Sir Thomas Lewis preferred to make his own definition—namely, "a malady in which the fingers and toes become periodically pale or cyanotic, and in which, after many winters of repeated attacks, the terminal portions of the digits may be lost by a process of dry gangrene." In this malady the main vessels affected were the arterioles of the parts involved, and the primary cause of the disease was in those vessels, not in the nervous system. Sir Thomas Lewis showed how it was possible to exclude the venous system from participation, also how rare was the evidence that the main arteries of the limb were affected, and he described a number of experiments showing, for example, that loss of the circulation to the tip of the finger could be produced by cooling the end of the finger itself in water, by cooling simply the middle portion of the finger, or by cooling the base of the finger—in fact, by cooling any portion of the finger which held a convenient stretch of digital artery. When the cyanosis disappeared from the fingers of patients owing to the warmth of the room it was not to be supposed that the attack had ended; in many of these patients there was scarcely an "attack," these small vessels being always in spasm, though from time to time a little extra "pinch" occurred, when the phenomena became manifest—or more manifest—clinically. In the United States Raynaud's phenomenon had been treated by excision of portions of the sympathetic nervous system. No doubt sympathectomy, in which the sympathetic nerves were found and excised, would lead to a very great improvement in the condition of the patient; he offered no criticism of the surgical operation, but the conclusions which were held to follow from that operation—that the condition was due to a vasomotor impulse—were unjustified. The observations on which he had been engaged led him to the view that the real cause of the malady was a local defect in the vessel, whereby cold acted unduly upon the vessel wall. Some rearrangement of ideas about the mechanism of Raynaud's phenomenon appeared to be necessary. The cause was a local one, and it lay in the parts of which the patient complained. It was not a general arterial phenomenon, so far as could be determined; the defect was in the small vessels, and it was only because the temperature effect upon these vessels was reinforced from time to time by increase in the nervous tone that the idea that the malady was primarily a vasomotor one had arisen.

THE NATIONAL RADIUM FUND.

THE Privy Council has now approved a charter constituting a body of Trustees to hold the National Radium Fund, and defining the duties of the administrative body of experts to be known as the National Radium Commission. Until the Great Seal is affixed the charter is technically in draft only, but we understand that the necessary letters patent to give it full legal effect will be issued almost immediately. The provisions of the charter, and the constitution of the body of Trustees and the National Radium Commission, follow the lines foreshadowed in our leading article on May 4th (p. 820). The Trustees will consist of the Lord President of the Council, the Minister of Health, the Secretary of State for Scotland, the President of the Royal Society, the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, the Chairman of the Central Liaison Committee of the Voluntary Hospitals in Scotland, the President of the Royal Society of Medicine, and the President of the British Medical Association, with power to co-opt as additional Trustees two medical members of the National Radium Commission on the nomination of the Commission itself, and not more than three other persons. The titular heads of the medical profession in Great Britain—namely, the occupants for the time being of the offices of President of the Royal College of Physicians of London, President of the Royal College of Surgeons of England, President of the Royal Society of Medicine, President of the British Medical Association, President of the Royal College of Physicians of Edinburgh, President of the Royal College of Surgeons of Edinburgh, President of the Royal Faculty of Physicians and Surgeons of Glasgow, Regius Professor of Medicine at Oxford, and Regius Professor of Physic at Cambridge—are empowered to nominate a panel of not fewer than twelve persons having special knowledge of the use of radium in medicine, from which number six will be chosen by the Trustees to form the majority of the members of the National Radium Commission. The Commission will comprise, in addition, a chairman appointed by the Trustees and four members nominated respectively by the Minister of Health, the Secretary for Scotland, the Medical Research Council, and the Department of Scientific and Industrial Research. It will come into existence only when the six members chosen from the panel of experts have been appointed. The charter provides that the Trustees shall hold the funds and buy therewith radium for use by the Commission. The Commission, as an administrative body, will deal with the distribution and use of all the radium held by the Trustees, having regard to the advancement of knowledge, treatment of the sick, and economy in use; in particular, it will be authorized to consider and approve plans submitted to it for the use of radium for the purposes of medical treatment and research. The members of the Commission will be appointed for four years, and be eligible for reappointment one year after retirement; the chairman, however, may be reappointed immediately. The Commission will arrange with the National Physical Laboratory at Teddington for the custody of radium not actually in use for medical purposes, for its preparation in a form ready for use, and its recovery from such preparation when returned from loan.

SLUMS AND CRIPPLES.

THE current number of *The Cripple*, a quarterly review, takes the form mainly of a special number dealing with "the slum problem." It contains some important articles on a subject which all the political parties put into their programmes during the recent electoral campaign, and which has since appeared in the King's Speech as one to which the Government is to direct immediate attention and presumably to attempt legislation. The two most important books of a general character on this subject are those which have recently been reviewed in these columns—*The Slum Problem*, by Mr. B. S. Townroe (December 1st, 1928, p. 998), and *How to Abolish the Slums*, by Mr. E. D. Simon, now happily once more a *member of Parliament* (March 2nd, 1929, p. 408). Each of these writers has a short but suggestive article in *The Cripple*. There is a noteworthy article also by Mr. Frederick Watson, the editor, on "The slum mind," which should clear away some sentimental notions, and in which he shows that it is apathy and contentment rather than wickedness and unhappiness which characterize the slum dweller, and that cottages in a picturesque village may be worse than any house in an urban courtyard. Probably the most important contribution is that by Mr. Harold Stannard, entitled simply "The slums." It puts in small compass the facts, the difficulties, and the common sense of the situation with regard to slum clearance and reconditioning. "If it has taken ten years," he says, "to build houses for people who wanted them and had the means to pay for them, how long will it take to rehouse a substantially poorer population

with no general desire to leave its present inadequate homes? . . . A demand for rehousing will not be generated among slum dwellers unless or until the causes which produce slums are precisely analysed and vigorously attacked." The cause is, in a word, poverty leading to overcrowding. But Government drive and lots of money will not by themselves solve the problem. "If we build another million houses at rents of ten shillings a week and upwards we shall not shift the slum population." The need is for houses to be let at from six to eight shillings. Nor is it true that it is only the slum mind that makes the slum. "There is truth in the dictum that the confirmed slum dweller will wreck any decent house to which he is transported. So strongly has this fact been appreciated by the municipality of Amsterdam that on demolishing old houses it sends their inhabitants to live for a while in a special building under continuous observation before drafting them to its new houses. Though the slum mind tends to perpetuate the character of its surroundings, it is a more fundamental truth that in the first instance the slum made the slum mind." It is naturally to the child born into the slum that most sympathy will be directed. Mr. E. D. Simon has estimated that there are some two million children whose environment causes them to need our social services, and at the same time forbids their deriving proper benefit from them. The slums levy a cruel toll on young life. The municipality of Glasgow, where overcrowding was specially acute, adopted its housing scheme in 1922. In that year 3,336 cases of pulmonary tuberculosis were moved to the city's hospitals. Three years later this figure was reduced by 742, or nearly a quarter. Consumption, rheumatism, deformity, can never be abolished while slums exist. A child may be taken to an orthopaedic clinic or hospital, but he must perforce often return to a one-room home, where there is no peace and but little of those three essential needs, air, light, and water. All the articles named deserve attention, and that by Mr. Stannard might well be reprinted and sent to every member of Parliament and town and county councillor.

STEPHEN HALES: PHYSIOLOGIST AND BOTANIST.

In June, 1927, when Corpus Christi College, Cambridge, was celebrating the 250th anniversary of the birth of Stephen Hales, D.D., F.R.S., Dr. A. E. Clark-Kennedy gave an address upon the life and work of this remarkable man. Overwhelmed by the number of facts he had collected, Dr. Clark-Kennedy has now brought them together into a book.[1] The original dissertation was summarized at length in our issue of June 18th, 1927, and the far-reaching effects of Hales's ingenious experiments on the circulation of the blood, the movements of sap, and growth in plants and animals were fully set forth. A description was given also of his system of ventilators, an invention which was applied to ships, hospitals, and prisons, and helped to reduce the mortality amongst inmates of such places as Newgate. But the great range and ingenuity of his experiments in these matters did not prevent Hales from devoting attention to many minor problems. He invented a winnowing machine, and a pair of forceps for extracting stones from the bladder. He recommended that airholes should be placed in the outer walls of ground-floor rooms, and teacups at the bottom of pies to prevent the syrup from boiling over. He taught a princess how to spread out and preserve Red Sea mosses. He made inquiries into the use of tar-water as a remedy, and examined the principal purging waters, especially that of Jessop's Well. He showed that the much-extolled waters of Glastonbury and of Godstone possessed no other properties than those of common spring water; and though he unfortunately upheld the claims of Mrs. Joanna Stephens to dissolve urinary calculi with a decoction of swine-cresses, soap, herbs, and calcined snails, and though he himself gained the Copley medal of the Royal Society for the least creditable part of his scientific work—his experiments on calculi—he was instrumental in exposing sundry quacks in the cure of this disease. With all this work he found time to be clerk of the closet to the Princess Dowager, and to carry on the duties of parish priest with great energy and thoroughness. He died at Teddington on January 4th, 1761, in the eighty-fourth year of his age.

APPOINTMENT OF PRINCIPAL MEDICAL OFFICERS TO LONDON COUNTY COUNCIL.

THE London County Council recently resolved, as announced in our issue of June 15th (p. 1092), to increase the staff of its public health department by three principal medical officers, in view of the magnitude of the duties to be undertaken in respect of transferred functions under the Local Government Act. At its meeting on July 16th, on the recommendation of the Public Health Committee, the following candidates were selected for the posts: Dr. J. A. H. Brincker, a senior medical officer on the council's staff, to be promoted to take charge of the work formerly carried on by the Metropolitan Asylums Board; Dr. William Brander, formerly of Hackney Hospital, to take control of the infirmaries which will come under the council; and Dr. W. Allen Daley, medical officer of health for Hull, to take over the general health work of the council, and to be medical officer for the council schools. The salary of these three officers will be an inclusive one of £2,000 a year, rising by annual increments of £100 to £2,500 a year. At the same time the maximum salaries of the chief officers of the council, including the medical officer of health (Dr. F. N. Kay Menzies), on whom additional work will be thrown, are to be raised from £2,500 to £3,000. Another appointment made is that of Miss D. E. Bannon, formerly matron at St. Mary's, who will be matron to the institutions and hospitals which the council will take over under the Act. Her salary will be £750, rising to £1,000 a year.

THE KING.

AT a consultation on July 9th between Lord Dawson, Sir Stanley Hewett, Sir Hugh Rigby, Mr. Wilfred Trotter, and Mr. H. L. Martyn, it was decided that a further operation on the King was necessary in order to provide adequate drainage for the residual abscess at the site of the empyema wound. This abscess communicated with the surface by an oblique sinus, which had become increasingly difficult to keep open. The size of the abscess (1½ inches across) and its position were determined by stereoscopic *x*-ray examination following injection of lipiodol through the sinus. The operation was performed at Buckingham Palace on July 15th by Sir Hugh Rigby and Mr. Trotter, under general anaesthesia administered by Sir Francis Shipway. The exposed ends of the rib resected on December 12th were cut away, and a portion of the next rib was also removed, thus giving free access to the abscess cavity, which, as Dr. Graham Hodgson's radiograms had suggested, was found to be circumscribed. His Majesty stood the operation very well, and both the general and local conditions are satisfactory. The immediate result of the operation is regarded as fulfilling all expectations, and we may hope that the cavity will now gradually, heal up from the bottom.

PREVENTION OF DAMPNESS IN DWELLINGS.

REPORT BY A SUBCOMMITTEE OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

IN December, 1926, the Science Committee of the British Medical Association approached the Royal Institute of British Architects with a request for its help in the investigation of the causes of dampness prevalent in certain types of dwellings. It may be recalled that the subcommittee appointed by the Science Committee to inquire into the prevention and control of rheumatic infection in children had presented its first report[1] to the Council of the Association in the previous July, but thereafter it continued to meet to discuss, somewhat informally, the lines on which any national effort to cope with the problems of juvenile rheumatism should proceed. Following discussions between certain members of the subcommittee and the Science Standing Committee of the Royal Institute of British Architects, the council of the Institute adopted the following resolution:

> The council of the Royal Institute of British Architects have had their attention called to the Report on Rheumatic Heart Disease in Children by the British Medical Association, and, having regard to the fact that it is in the public interest to eliminate dampness in all dwellings, they note with approval that the Science Standing Committee have appointed a subcommittee to investigate and report on this subject.

The subcommittee referred to in this resolution concerned itself not with any particular disease, but with the wider question of the causes and prevention of dampness in dwellings, and its report has just been issued in pamphlet form.[2]

The first evidence before the subcommittee was that presented by Dr. Reginald Miller and Dr. A. P. Thomson on behalf of the Science Committee of the British Medical Association. Dr. Miller discussed dampness in particular types of town dwellings and the stories thereby affected; Dr. Thomson gave evidence relating to the line of dampness in a district. The subcommittee reports that, while these witnesses were able to show the peculiarities of dampness either in a particular dwelling or district, they were not in a position to advance any reasons for the effects they observed. With a view to obtaining further evidence the subcommittee prepared a questionary which, on May 27th, 1927, was sent out by the Society of Medical Officers of Health to all its members. The aim of these questions was to ascertain the number and proportion of damp houses in each district, and, as far as possible, which causes of house dampness were most widely prevalent.

CAUSES OF DAMPNESS.

From the evidence before it the subcommittee was able to summarize the causes of dampness as follows:

1. Absence of, insufficiency of, or defects in damp courses, whether horizontal or vertical.
2. Absence of, insufficiency of, or defects in the covering of the ground over the internal area of the dwelling, or the covering of the ground immediately adjoining the dwelling.
3. Lack of, or insufficiency of, the drainage of the subsoil.
4. Porosity or the capacity of the material forming the walls to absorb moisture, or the construction of the walls.
5. Defects mainly due to lack of maintenance, but including some cases of faulty roof construction.
6. Condensation on internal surfaces of walls.

From an analysis of the extent to which the various causes operated in houses classified as (*a*) less than ten years old, and (*b*) more than ten years old, the subcommittee concluded that the causes of dampness in the latter arose chiefly from the original absence of a damp course or from insufficient maintenance, a view which is largely supported by the observations of each medical officer who forwarded information on the matter. In the houses less than ten years old the causes in order of magnitude were 4, 1, 5, 2, 3, 6, of the above summary. In respect of each of these causes the subcommittee makes the following comments and suggestions.

Damp Courses.

In view of the fact that all codes of building by-laws now call for an adequate damp course, the subcommittee is surprised to note the high proportion of cases of dampness in new dwellings due to the absence of, or defects in, damp courses. Such absence must imply failure to comply with the by-laws, the defects arising either from the same cause or from the use of materials of inferior quality. The subcommittee holds that stricter supervision of building in respect of damp courses is called for, care being especially necessary to prohibit the use of any materials other than those of proved durability. It points out that the difference between damp courses of reliable and those of inferior quality may not easily be detected by casual inspection, and raises the question of the advisability of subjecting damp-course materials to standard specification.

Floors and Sub-soil.

The subcommittee is of opinion that the extensive use of solid floors for small dwellings during the time when timber was scarce and expensive has probably increased the number of cases of dampness which arise from failure to cover the whole surface of the ground within the building, or from the use for such purpose of unsuitable materials. It points out that surface concrete is seldom completely impervious to moisture, and that in any kind of solid floor resting on a subsoil liable to dampness complete dryness can be secured only if a layer of hard, broken material, unable to conduct moisture by capillarity, is interspersed between the concrete and the soil. Such a layer, however, would be worse than useless if, for lack of subsoil drainage, the water-level could rise into it. Some by-laws require the use of concrete in all cases, others only "wherever the dampness of the site or the nature of the soil renders such a protection necessary," and the subcommittee suggests that, possibly, surveyors have been willing, on insufficient grounds, to dispense with this protection. In its view, surface concrete should be dispensed with only when there can be no doubt that the surface of the ground will be exceptionally dry.

Absorption of Moisture by Walls.

This cause of dampness is prominent both in new and in old houses, and the subcommittee considers that in post-war houses the majority of cases of penetration of damp from external walls has occurred where traditional solid brick or masonry, or solid concrete walls, have been employed. A large proportion of the "alternative" methods of construction have involved the use of a cavity wall construction, and, whatever their other defects, these methods may be considered to have been more effective than certain traditional systems in preventing the access of moisture into houses. The surest way of protecting interiors from dampness, whether from water passing in under a head or penetrating by the operation of capillary forces, is to provide a continuous cavity in external walls. It is extremely difficult to guard against the possibility of shrinkage cracks developing in the external cement renderings, often applied to outer walls built of solid brick or masonry, and, once these cracks appear, water entering through them will tend to evaporate from the more porous interior face, and produce a cold wall. The subcommittee holds that overhanging eaves have far greater value than is generally appreciated in keeping external walls dry, and it deprecates the present tendency to cut down the overhang.

Defective Maintenance.

Defective maintenance naturally shows itself to a greater extent in old buildings. It is impossible to differentiate precisely between cases due solely to want of repair and those which are aggravated by original defects in the structure; there is no doubt, however, that much damp is due to inadequate maintenance of roofs, rain-water gutters, and the like. The subcommittee suggests that local authorities may in this matter play an important part by calling upon, and if necessary compelling, owners to keep their property in repair. Such measures, far from imposing hardship, would in the end secure the greatest economy. In general, sufficient care is not taken to construct thoroughly water- and snow-proof roofs,

[1] The report was printed in full in the *Supplement* to the *British Medical Journal* of July 3rd, 1926.

[2] Report on Damp Houses. London: The Royal Institute of British Architects, 9, Conduit Street, W.1. Price 6d.

and it is probable that the use of various types of pantiles or interlocking tiles treated with unsuitable pitch has been responsible for the penetration of moisture into dwellings. Similarly, insufficient pitch and perishable nails, or inadequate lap, are frequently sources of danger when flat tiles and slates are employed in the construction. The practice of bedding tiles down on to gable walls may, in certain circumstances, lead to the penetration of dampness; furthermore, tiles which are satisfactory over the roof surface may, when bedded in mortar on the wall, be sufficiently permeable to transmit moisture by capillarity. The subcommittee considers unsatisfactory the use of cement fillets alone between roofs and walls or other vertical surfaces. The shrinkage of roof timbers causes movement, and cement and cement mortar tend to shrink on drying; wherever such movement or shrinkage may provide a passage for moisture cement should be banned.

Condensation of Moisture on Walls.

While condensation on the more impervious surfaces occurs usually in the form of running water, on a more porous surface the condensed moisture may be absorbed, and thereby rendered invisible. As it is on the walls of low temperature that condensation occurs, the construction should be such as to permit of rapid heating of interior surfaces.

CONCLUSIONS.

In concluding its report, the subcommittee expresses the conviction that no consideration of economy can justify the sacrifice of treatments necessary to secure a reliable waterproof shell for buildings and adequate damp-course protection. It strongly recommends that the erection of dwelling-houses should be subjected to stricter technical supervision, whether by architects or by properly qualified officers of local authorities. It also draws attention to the fact that present by-laws do not provide a complete safeguard against the construction of unsatisfactory buildings, and holds, therefore, that deficiencies in the Public Health Act should be remedied by suitable amendments.

THE CAMPAIGN AGAINST VENEREAL DISEASE.

CONGRESS IN LONDON.

THE fourth Imperial Social Hygiene Congress, of which a preliminary report appeared in last week's issue (p. 61), devoted its first session, on July 8th, to a consideration of the international situation with regard to venereal disease.

The International Situation.

Dame RACHEL CROWDIE of the Social Question Section of the League of Nations read a paper on the activities of the Advisory Committee in relation to prostitution. Signatures on behalf of twenty-two countries had been appended to the protocol for the suppression of traffic in women, and an inquiry had been conducted into the facts of the traffic in about thirty countries. Of forty-seven countries which had adopted the system of licensed houses, twenty-eight had abolished it, and of the rest, fourteen or fifteen had set up commissions of inquiry with a view to its abolition. Closer co-operation between nations, particularly in the sharing of information about such matters as the activities of bogus employment agencies, would help to reduce the amount of prostitution. The ages of marriage and consent should be raised, and there should be stricter punishment of men living on the immoral earnings of women. Finally, it was urgent that there should be better moral and biological education for young people. With regard to the already infected, nations must choose definitely between compulsory notification and treatment, and the voluntary method coupled with secrecy.

Sir GEORGE BUCHANAN, representing the Health Section of the League, explained the methods adopted for securing continuous treatment of infected seamen of the Mercantile Marine by means of personal cards, which were carried by the sailor from port to port, and contained full particulars of diagnosis and treatment. Colonel L. W. HARRISON, the British expert delegate to the Health Organization, dealt with the co-ordination and development of work in connexion with serological tests and the scientific treatment of syphilis. He emphasized the difficulties of securing reliable standard tests of syphilitic infection.

In reply to a delegate from Scotland, who urged the necessity for compulsory notification and treatment of venereal diseases, Mr. E. B. TURNER suggested that public opinion in Great Britain was not yet sufficiently developed to justify the council in pressing for legislation on the lines suggested; indeed, compulsion might undo much of the good work already achieved by voluntary methods.

Colonel L. W. HARNETT, representing the Government of Bengal, informed the conference that at the port of Calcutta the recreational facilities for seamen were being extended, and that in the autumn a new club would be opened, which would include a venereal diseases treatment centre.

Social Hygiene and the Services.

Mr. E. B. TURNER took the chair at the afternoon session, when the congress considered the efforts made to reduce venereal diseases in the Navy, Army, and Air Force, and the Mercantile Marine. The discussion was opened by Surgeon Commander RIVAZ, who dealt with the subject in its relation to the Navy. The incidence of all forms of these diseases, he pointed out, was lowest in 1914 and 1915. It increased during the war and after the armistice. Since then there had been a drop each year, which promised to continue as the result of the preventive measures adopted in the Navy. Statistics were given to illustrate the value of early disinfection; at the same time, Commander Rivaz emphasized the point that one of the chief causes for the decline was the diminished consumption of alcohol obtaining throughout the service. Squadron Leader STARKEY, representing the Air Ministry, said that the temptation to which the Royal Air Force was exposed was less than in the case of other services, as the most desolate spots were always selected as Air Force stations.

Admiral Sir REGINALD TUPPER, chairman of the British Council for the Welfare of the Mercantile Marine, said that his council was now taking definite and practical steps to promote the health of the merchant seamen throughout the world. At the National Conference on the Health and Welfare of the British Merchant Navy, which was held in May last, resolutions furnishing a programme for immediate adoption at home were passed unanimously. It was also agreed that committees should be constituted without delay in all the major ports of Great Britain by the co-operation of the port and local authorities, and of the voluntary organizations concerned; they would be able to link up the harbours and the towns and abolish the condition of segregation which was responsible for so much disaster in the lives of the seafaring population.

Dr. A. O. ROSS, venereal diseases officer, city and port of Liverpool, pointed out that merchant ships varied in class, from the Atlantic liner to small vessels engaged on short voyages. Efficient treatment reached its high-water mark in the liners engaged in the Far Eastern trade. Most of the patients at Liverpool came from the class of ocean-going tramps; the special conditions found in neglected cases came from this class. Most men of this type had no sense of responsibility; compulsion was the only real remedy for them. It would be of great help if all men signed on for a long voyage were examined for venereal disease. He did not believe that brothel regulation was a safeguard. One-third of the cases in Liverpool were of seamen infected abroad.

During the discussion which followed it was suggested that the inference to be drawn from Commander Rivaz's figures was that the incidence of disease depended upon the cleanliness of the civil population, and that this was justification for the work of the local authorities in this country. Commander Rivaz was closely questioned as to the discharge to civil life of sailors who refused treatment and the basis of his statistics relating to the value of early disinfection.

Professor BOSTOCK HILL emphasized the difficulties which arose in dealing with the Mercantile Marine. Little was done on the voyage for the entertainment and instruction of crews; there was therefore a powerful temptation when port was reached, and this was increased where there were no regulations to prevent the invasion of ships by undesirable persons whilst they were in ports. The remedy was the formation of committees who would undertake the entertainment of crews during their leisure time ashore.

Compulsory Treatment.

On July 9th, with Professor A. BOSTOCK HILL in the chair, Dr. T. F. DEWAR, medical officer, Scottish Board of Health, raised the question of compulsory treatment. The worst problem was that of the sufferers who, having started treatment, defied all attempts to persuade them to resume. The three outstanding problems of the future were: the patient who attended too late, the patient who desisted from treatment, and the doctor whose training in relation to the venereal diseases was inadequate.

Dr. T. W. WADE, medical officer, Welsh Board of Health, emphasized the fact that in Wales a high proportion of patients ceased attendance before being discharged as cured. Record, showed, also, that very few patients found their way to centres of their own accord. Women, especially, must be sought out if they were to be brought under treatment.

Discussing the steps taken to deal with the problem in Australia, Dr. C. L. PARK, chief medical officer, Australia House, insisted that compulsory treatment had not encouraged concealment, and stated that 80 per cent. of defaulters resumed treatment under persuasion, no legal proceedings being necessary. He also emphasized the need for better education of medical students and the general public, and for teaching elementary physiology in schools.

The Hon. HERBERT GREENFIELD, agent in London for the Government of Alberta, explained that, in view of the predominantly rural nature of the province, although well-equipped clinics were open to all sufferers free of charge, patients in remote parts were treated by their local doctors at the Government's expense until they became non-infectious. A limited measure of compulsory treatment had been enforced against persons arrested on certain specified charges and found to be infected.

The subsequent discussion was almost entirely confined to pleas by Scottish delegates that Scotland should be permitted to experiment with compulsory treatment, at any rate of known defaulters. Mrs. NEVILLE ROLFE, after stating that the British Social Hygiene Council would not oppose an experiment in an area where public opinion was favourable to compulsion, suggested that statistics led to the belief that greater continuity of treatment was secured under the voluntary system.

A delegate from Southern India urged the conference to press for compulsory circumcision of all male children. Experience with a Mohammedan battalion, all of whom were circumcised, and a Hindu battalion, very few of whom were circumcised, seemed to indicate that the former kept very free from infection without being noticeably more moral than the latter.

Dr. W. G. CLARK of Glasgow recounted the case of 1,000 men sent on leave from Scapa Flow with prophylactic packets, only three of whom became infected, and those were too drunk to carry out the prophylaxis. Against this, however, Mrs. ROLFE urged the test carried out by the French army authorities, which showed that the incidence of infection was reduced more rapidly by hygiene teaching alone than by teaching combined with the issue of prophylactics.

At the afternoon session, after introductory remarks by Mr. L. S. AMERY, M.P., the congress resumed its study of progress reports and methods of treatment. The report from New Zealand stated that the knowledge that there was power to enforce treatment was a factor in persuading sufferers to continue until cured. There was evidence, however, that all practitioners did not, as required by law, notify all cases of patients ceasing to attend until discharged.

During the discussion, Colonel HARRISON rebutted the opinion expressed in certain quarters that infected persons who evaded treatment were more likely to escape general paralysis than those who submitted themselves to treatment. The result of a questionary circulated on an extensive scale showed that this view was without foundation.

Methods of Reaching the Infected Population.

The chair was taken during the morning session of July 10th by Mr. SOMERVILLE HASTINGS, M.P., and Colonel HARRISON opened the subject of the attraction to treatment and the rendering non-infective of the infected population. Education of the public had already had an important effect, and more infected cases now came to treatment at the earliest moment. With regard to liaison between venereal disease and other public health services, Colonel Harrison suggested the provision of adequate treatment at maternity and child welfare centres for cases of infection discovered there. He stressed the importance of venereal disease officers being imbued with the public health ideal rather than with the "hospital out-patient attitude." It was important that there should be good relations between the venereal disease officer and the local medical officer of health. Attendances depended largely upon the personality of the venereal disease officer and his staff.

The CHAIRMAN then read a paper submitted by Mr. S. B. JONES of St. Kitts. The largest proportion of the infected population of St. Kitts, he said, consisted of agricultural labourers, domestic servants, porters, and boatmen, descended from African slaves. The presence of venereal diseases among them was due to ignorance, low standards of living, and bad environment. To attract them to treatment it was necessary to explain to them the nature of these diseases, and how they affected their social life and wage-earning capacity. The campaign should be in the hands of a single physician who, by moral suasion, would urge the infected to persist in treatment, but, failing this, notification and compulsory treatment would be enforced.

Dr. HENRY CLUCKMAN, director, Johannesburg City Council Special Treatment Centre, pointed out the difficulty, by reason of expense, of having separate clinics with full-time medical staffs in small communities. On behalf of the Birmingham Public Health Committee, Miss H. BARTLETT stated that Birmingham had found it much easier to obtain attendance at ordinary hospitals, maternity centres, etc., than at special clinics. Mentally deficient and insane persons presented a special problem. In Birmingham tests were made for syphilitic infection upon every person admitted to an institution.

Dr. MARJORIE SMITH-WILSON urged the desirability of having a special social worker attached to each treatment centre for the purpose of examining the social background of the patient in such matters as the ability to pay train fares, the securing of affiliation orders or separation from an infected husband or wife. There was also the question of the provision of hostels for residence during treatment and pending rehabilitation, and Dr. Smith-Wilson described some successful efforts in this direction. The important factor was that inmates should, as nearly as possible, enjoy a normal existence. Boys, in particular, were very poorly served in this respect.

The Position in India.

The chair was taken at the afternoon session by Sir ATUL CHATTERJEE, High Commissioner for India.

Dr. A. B. SOUSA, assistant director of public health in the United Provinces, said that in the Provinces about 20 per cent. of the population was infected. On the other hand, there had been a big drop in the number of cases among British troops. Many municipalities were framing by-laws for the confinements of prostitutes in outlying quarters, and the Government had passed legislation prohibiting girls from being brought up for immoral purposes among the Naik families. Another bill was now before the council making the prohibition general.

Colonel HARNETT stated that one of the most effective means of checking venereal disease in Calcutta had been found to be the provision by employers of married quarters for labour from up-country districts. The great obstacle to effective propaganda was the illiteracy of 88 per cent. of the population. It was particularly necessary that the education of women should be pressed for; at the last census only 1.8 per cent. of native women were literate.

Sir ATUL CHATTERJEE said that, with a general improvement in the social conditions of India, knowledge of sex hygiene should not be difficult to spread, because there was far less squeamishness there than in the West in discussing sexual problems.

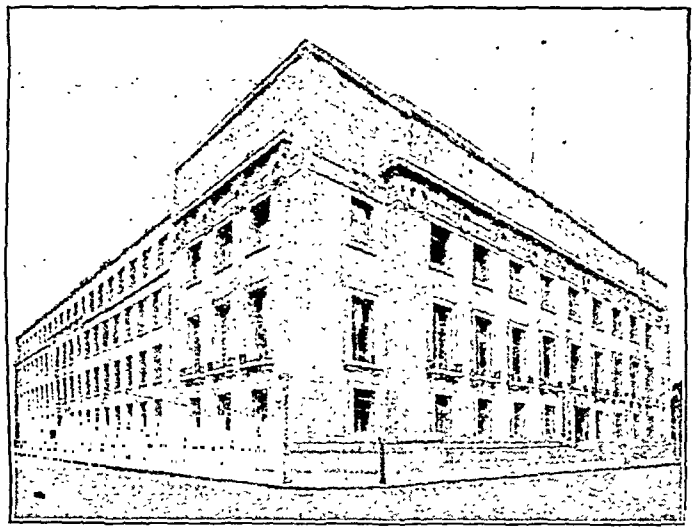
General HOOTON of the Government of Bombay said that, thanks to the visit of a delegation from the council, special equipment for the treatment of venereal diseases had been incorporated in the new hospital constructed at Bombay. The crux of the whole problem in India was female education. Westerners must not judge India from Miss Mayo's books, which, although based on facts, took no account of enlightened Indian opinion, and had made a large number of Indians very touchy about reform.

THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

OPENING OF THE NEW BUILDING.

THE new building of the London School of Hygiene and Tropical Medicine, which was opened by H.R.H. the PRINCE OF WALES, on July 18th, was made available for inspection by representatives of the press four days before the official ceremony. Sir HOLBURT WARING, chairman of the court of governors, presided over the informal proceedings, and after brief addresses by Dr. ANDREW BALFOUR, director of the School, Professor W. W. JAMESON, director of the division of public health, and Mr. VERNER O. REES, one of the architects (the other being Mr. P. Morley Horder), the visitors were conducted over the structure, which was receiving the finishing touches at the hands of busy workmen.

This magnificent building, which has been three years in erection, occupies a site in Bloomsbury, just north of the British Museum and south of University College. It is one of the largest of modern buildings in London, and a noteworthy addition to academic architecture. The outstanding impression, both within and without, is of great plainness and purposefulness. The exterior, which on one side faces Gower Street, is plain almost to severity. The only decorative notes are the gilded bronze insects, carriers of *tropical diseases*, which enrich the balconies of the first-floor windows, some allegorical sculpture over the main entrance in Keppel Street, and the frieze running round the building, bearing the names of twenty pioneers in hygiene and tropical medicine. The interior has been arranged to embody two large open courts, which not only serve as pleasant promenades, but give light and air to the surrounding rooms.



Before describing the general arrangement of the interior it is necessary to recall the circumstances which have led up to this foundation. The School is the outcome of the recommendations of the Athlone Committee in 1921 for the establishment of a central institution, affiliated to the University of London, wherein full provision should be made for instruction in all branches of preventive medicine. It has been made possible by the gift of the trustees of the Rockefeller Foundation in New York, who offered the Ministry of Health £460,000 for the purchase of the site and the erection and equipment of the building, on condition that the British Government should contribute adequately towards its maintenance. The primary function of the School, as Dr. Balfour explained on July 14th, was to train medical men and women desirous of entering the public health services in this country or abroad and to undertake research work in preventive medicine.

Before the preliminary plans were approved, however, its role was enlarged by union with the London School of Tropical Medicine, the institution which for many years occupied premises at the Albert Docks, and after the war removed to Endsleigh Gardens. The union, as Dr. Balfour said, was timely, for there is now recognized to be no sharp dividing line between the diseases of hot climates and those familiar in temperate latitudes. Therefore this new London School of Hygiene and Tropical Medicine, which was incorporated as such by Royal Charter in 1924, is charged with the duty of continuing and enlarging the instruction given in the old School founded by Mr. Joseph Chamberlain thirty years ago, and of providing facilities for research on the lines which have made that School famous the world over.

Divisions of the School.

The work of the School has been arranged in the following divisions, each in charge of a director and staff: public health, including a section devoted to the physiology of hygiene, whose activities will bear closely upon industrial problems; epidemiology and vital statistics; bacteriology and immunology; biochemistry, including a department for chemistry as applied to hygiene; medical zoology, embracing the departments of protozoology, helminthology, and entomology; and, finally, tropical medicine and hygiene, of which Dr. Balfour himself has charge, and which embraces the all-important clinical work in diseases of the tropics, for which facilities are afforded by the Hospital for Tropical Diseases in Gordon Street close by.

Description of Building.

The building consists of two principal parts, the first comprising the rooms for public uses—namely, the library, museum, and lecture theatre—and the second the accommodation required for teaching and research, including the laboratories, workshops, and animal quarters. The library, panelled in oak, is a spacious apartment, with a balcony, and the aim is to make it a large and representative library of hygiene in the widest sense of the word. The museum also occupies a very large amount of space. It consists of three parts—namely, sanitary hygiene, hygiene in the popular sense, and tropical medicine. It marks a new departure in the sense that the assistance of various large commercial interests has been sought and generously granted. A number of leading firms whose business is concerned with public health activities of various kinds have co-operated to present to the museum exhibits of educational value. Both the library and the museum owe their nucleus to the collections of the old London School of Tropical Medicine.

The lecture theatre, which seats about 250, must be one of the finest in any university. Behind the screen is a large cinematograph projector. The comfort of the seats, with the collapsible desk for note-taking, the provision for lighting and ventilation, the arrangement for instantaneous darkening of the windows, are all on the most modern plan. This theatre, like the library and museum, will be available for public uses, and here it may be said that members of the public health services, who also have a common room placed at their disposal, will be welcomed at the School at all times, not only at the lectures given by the staff, but also at a series of special lectures to be given by experts on public health problems.

The laboratory accommodation is planned on the same generous scale. The benching and many other items of equipment in the laboratories, large and small, have been standardized, and every mechanical service has been provided. The pipes for power, gas, steam, light, and hot and cold water have been left exposed for free access, and painted in different colours to aid identification. Every provision for the convenience of the 250 or 300 students who, it is hoped, may be working at these benches has been installed. In addition to two very large laboratories, one of them accommodating eighty students, there are what seemed to be a quite bewildering number of small

rooms for special research, as well as class-rooms and workshops. One apartment is equipped with calculating machines for assisting in statistical investigations. Then there are the extensive animal quarters, including a detached building of unusual design, intended as an insectarium. The whole of the School is warmed by radiant heat from heating coils embedded in the ceilings. The flooring of the public rooms and administrative offices is of cork, and that of the laboratories and corridors of teak blocks. At every turn one comes upon some dextrous device—a new kind of door handle, a specially designed gas-fire, a lighting fixture of very unusual type.

It is worth while on leaving to glance at the names on the frontage. The British names are Chadwick, William Farr, Edward Jenner, William Leishman, Timothy Richard Lewis (who discovered the trypanosome bearing his name), James Lind (physician at Haslar in the eighteenth century), Lister, Manson, Edward Parkes, Sir John Pringle, Sir John Simon, and the great Sydenham. The Americans are Hermann Biggs, the leading figure in public health work in New York early in the present century, General Gorgas, Walter Reed, who carried out important work on typhoid in the Spanish-American war, and Shattuck, described as the Chadwick of the United States. The Continental selections are Johann Peter Frank, a name almost forgotten in this country, Koch, Laveran Pasteur, and von Pettenkofer of Munich who has been called the founder of experimental medicine. There are plenty of spaces left, and no doubt the School itself will in time furnish other names, perhaps names to eclipse all forerunners.

It was announced that the first course of training in public health would begin in the new building on September 30th, and that a curriculum had been arranged which would give students a more comprehensive view of the whole field of public health than had hitherto been possible.

England and Wales.

Dreadnought Hospital: Opening of Laboratory and Nurses' Home.

AT the Dreadnought Hospital, Greenwich (Seamen's Hospital Society), on July 15th, the Duke and Duchess of York opened the new pathological laboratory and nurses' home. These buildings are the most recent outcome of the fund inaugurated by Viscount Devonport in 1915 for the improvement and extension of this hospital. The response to Lord Devonport's appeal was universal, being prompted by the gratitude felt in all parts of the Empire, especially during the war, to the men of the mercantile marine. The pathological laboratory has been built to serve the hospital and also to carry out the bacteriological work of Greenwich and four neighbouring boroughs. The new building is planned in three sections. The laboratories with their administrative offices, library, and museum, are placed around a central entrance hall and staircase. On the south side of the building are the operating and post-mortem rooms, mortuary, and chapel, and on the north side the workshops and other necessary accommodation, such as an animal room. The new nurses' home is situated near the fine gardens of the Royal Hospital School, and includes a private bedroom for each nurse. The whole of the work of the two buildings, which were greatly admired, was designed and executed by the architect, Sir Edwin Cooper. The Duke of York, after declaring the buildings open, said how glad he was to feel that the "Dreadnought" was now equipped with an adequate pathological laboratory, which was available for the neighbouring municipal boroughs, as well as for the needs of the hospital itself. The people in the neighbourhood of Greenwich had helped the "Dreadnought" splendidly, through the Seamen's Hospital Aid Committee, and he was glad to feel that the hospital was able also to help them. In addition to the erection of these new buildings a certain amount of the Devonport fund had been put aside for endowment; this was a wise policy, of which he heartily approved. It was the policy of the Seamen's Hospital Society, which aimed at freedom from indebtedness for its network of establishments. It might not be generally known that this was the largest group of seamen's hospitals in the world; it included seven establishments, and required the raising of £95,000 every year to keep the institutions going. He paid a tribute to the skill and devotion of the medical staff, both honorary and resident. All concerned were indebted to the medical officers for their services.

On the evening of the day of the opening of the laboratory, the London School of Clinical Medicine entertained Lord Devonport at dinner at the Langham Hotel. Professor R. T. Hewlett, who presided, reminded the gathering of the great services rendered by their guest since 1915, when he stepped into the breach and organized the fund which had been such a splendid success. The buildings now erected would be a lasting memorial to the men of the mercantile marine, and they would also help to continue the tradition of the "Dreadnought" for pathological research, although in the past such research had often been carried on under the most difficult conditions. Lord Devonport explained that it was when he became chairman of the Port of London Authority that the needs of the Seamen's Hospital were brought home to him. He recognized how many urgent developments were held up on account of lack of funds. The very first week after the appeal was launched brought in a sum far in excess of the £10,000 which had been anticipated. Mr. Percival Cole, F.R.C.S., the dean of the school, maintained that the London School of Clinical Medicine had sustained the prestige of the Seamen's Hospital Society throughout the world. In these days it was not sufficient for a charity to be deserving; it must be backed by professional ability. He envisaged a closer liaison between the clinical and pathological departments. Sir John Rose Bradford, F.R.C.P., responding to the toast of "The Guests," which was proposed by Sir Arthur Clarke, chairman of the Seamen's Hospital Society, said that he could speak as one who had been and still was attached to the staff of the hospital. All who had been at any time connected with the "Dreadnought" were impressed by the camaraderie and good fellowship between the governing body and the staff.

New Pharmacological Laboratories at the University of Manchester.

On July 10th Mr. F. H. Carr, late president of the Society of Chemical Industry, opened the new laboratories which Messrs. Benger's Food, Ltd., have presented to the Medical School of the University of Manchester. The new laboratories are for the study of pharmacology, pharmaceutical chemistry, and biochemistry in its relation to pharmacology. They consist of a room suitably equipped for experiments on animals and man, with a preparation room attached; a biochemical laboratory; a pharmaceutical chemistry laboratory with separate balance and furnace rooms; a demonstration theatre to accommodate some fifty students; private laboratories for the head of the department and a lecturer; and a room to be used as a library and secretary's room. There are three small rooms near by in which animals can be housed under ideal conditions. This extension has been rendered possible, first, through the removal of the department of pathology to York Place, where it is in more immediate contact with clinical work and the departments of bacteriology and public health, and secondly, through the generosity of Messrs. Benger's Food, Ltd., who have given the University £2,000 to furnish and equip these laboratories, in memory of Frederick Baden Benger, the founder of the firm. This department of the Medical School owes its present efficient condition to the influence, material support, and devotion of the late Professor D. J. Leech, who organized and fully equipped it for its needs in 1884. He furthermore endowed the Leech Chair of Materia Medica and Therapeutics, which he held himself for some years, making thus a valuable addition to the endowed chairs of the school. He was succeeded in it by Professor R. B. Wild. The Leech Library (a departmental library for material medica, therapeutics, and pharmacology) was founded in memory of Professor Leech. Professor Wild retired in 1927, and the chair has not been filled since, but a readership has been instituted for the present, and this is held by Dr. A. D. Macdonald. The University, with its fine school of chemistry, its well-equipped school of physiology, and the magnificent clinical facilities of the Manchester Royal Infirmary, should provide a fruitful

field in which pharmacology and pharmaceutical chemistry should flourish. It is hoped that the present scheme will provide a modest beginning out of which a school of pharmacology and pharmaceutical chemistry may grow, a school comparable in its influence with the other great schools of the University.

The first systematic course on pharmaceutical chemistry was given in 1824 by John Dalton, F.R.S., then president of the Literary and Philosophical Society; it consisted of about fifteen lectures, delivered in the evenings at 7 o'clock. It is on record that the lecturer, after explaining the first principles of chemistry, proceeded to apply them to investigations respecting materia medica, and to other purposes relating to the profession. According to a printed syllabus the lectures dealt with heat or caloric, constitution of bodies, chemical syntheses and analyses, simple or elementary gases, elementary solids, compound bodies, alkalis, acids, etc., earths, sulphurets, metals, the vegetable kingdom, and the animal kingdom. The lecturer received fees amounting to £27 8s. 9d., but his expenses were £10 10s. He continued his connexion with the Medical School for at least six sessions; in the later period he had in each session three separate classes attended by eight or nine students. Benger's preparations owe their origin to the endeavour of Sir William Roberts in the eighties of last century, as he told the Royal College of Physicians, to prepare a predigested and more palatable food of different nature to what was then known as "Darby's peptonized fluid meat."

Rat Extermination in the Port of Liverpool.

The occurrence of cases of plague in ports at which a considerable proportion of the cargoes destined for this country are loaded—above all, in the ports of South America, West Africa, and India—indicates how vital is adequate extermination of rats, both on board ship and in dock areas, for the protection of the population against an epidemic. Dr. A. A. Mussen, medical officer of health to the Liverpool Port Sanitary Authority, in his report for the year 1923, points out that it was a realization of this fact and of the fact that, to be effective, measures designed to combat the incidence and spread of plague must be world-wide in their application, which brought about the International Sanitary Conference of 1926. Among the general provisions laid down by the conference is one requiring that "all ships, except those engaged in national coastwise service, shall be periodically deratized, or be permanently so maintained that any rat population is kept down to a minimum." In Liverpool, vessels which have been "deratized" are granted a deratization certificate, or, if found by the Port Authority to be free from rats, a deratization exemption certificate. These certificates are valid for six months, at the end of which the vessel is re-examined, unless it has become definitely reinfested in the interval. The Port Authority issued the first certificate on October 5th, 1928, and up to the end of the year twenty-five deratization certificates and eleven exemption certificates had been issued. Dr. Mussen records that during the past few years a very marked diminution has been observed in the number of rats found on vessels entering the Port of Liverpool, the average number of rats per ship having fallen from 68.6 in 1914 to 14.7 in 1928. Vessels trading with River Plate and Brazilian ports—owing largely to the fact that they carry cargoes of grain—are found to contain a high average number. Vessels arriving from the west coast of South America, North America, New Zealand, and Australia, on the other hand, show a reasonably low figure, mainly, perhaps, on account of the strict insistence on periodic fumigation which has been the policy of the United States and Australasian Governments. Cargoes unattractive to rats include hardware, fruit in boxes, and other products that can be so tightly packed in the holds that no room is left for the rats to move about; attractive cargoes, besides grain, are palm kernels and sugar. No adequate returns are available to show the relation between rat incidence and the number of cats on board, but of 87 ships arriving in Liverpool during December 78 carried cats, and, according to the Authority's catchers, they were also carrying a certain number of rats. The general experience suggests that cats are of value for deratizing purposes only when other food is scarce—a comparatively rare occurrence. "Trapping," though a most important method, must necessarily prove less valuable than fumigation, simply because in the time available to the catchers it is usually impossible completely to rid a vessel carrying more than a small number of rats; it has, on the other hand, the advantage of being a less expensive method than fumigation. The private catchers of the shipping companies are reported to have caught 22,047 rats during 1928. In fumigation lies the only sure way of completely ridding a vessel of rats; the agent generally used is sulphur dioxide, but hydrocyanic acid has been used in a certain number of cases. To maintain the diminution in the number of rats per ship Dr. Mussen suggests the following measures: (1) greater care at foreign ports in the loading of cargoes known to be "rat attractive," in order that as few rats as possible may be allowed to enter the vessel; (2) the "rat-proofing" of all vessels; (3) the continuance of the present measures with regard to trapping; (4) periodic fumigation of vessels engaged in carrying "rat attractive" cargoes, and other vessels, when the rat population is abnormally increased.

The Danger of Water Shortage.

The Minister of Health, Mr. Arthur Greenwood, received a deputation on July 12th from the British Waterworks Association. The speakers emphasized the danger of a grave shortage of water unless very heavy rainfalls occurred in the near future. In some parts of England, and especially in Lancashire and Yorkshire, the situation was already giving cause for anxiety, and in certain towns the water reserves were now disquietingly low. The deputation suggested that emergency legislation should be introduced to enable economies to be effected by reducing the volume of "compensation" water, much of which at present ran to waste, and urged that the Minister should take steps to impress upon the public the need for drastic economy in the use of water. The Minister said, in reply, that he fully realized the gravity of the situation caused by the present very exceptional drought. While there was no possibility of introducing legislation before the recess, he was anxious to do all that he could to help water authorities to meet their difficulties. He proposed, therefore, to issue at once a memorandum drawing attention to the need for economy and suggesting the precautions that should be taken. He hoped that the interests concerned would appreciate the seriousness of the situation and be willing to come to agreements with water undertakers in the matter of compensation water, and he trusted that the general public would exercise strict economy in their consumption of water for domestic and garden purposes. This memorandum, issued on July 16th, emphasizes the value of forming advisory regional committees, supplementing existing water supplies, and guarding against pollution. Other points commended for immediate attention are the prevention of waste, the temporary reduction of compensation water, and the use of non-potable water for the flushing of drains and street watering.

The Osler Club.

The sixteenth meeting of the Osler Club was held at 27, Wimpole Street, London, on the evening of Friday, July 12th, to celebrate the eightieth anniversary of the birth of Sir William Osler. Sir Archibald Garrod delivered the second Oslerian Oration, on the power of personality. The orator dealt with personality from the point of view of medicine, of the practice of medicine, and as exemplified by Osler in the teaching of medicine. The discussion was opened by Dr. A. G. Gibson, and speeches were made by Dr. G. Feine, Professor Francis Fraser, and Mr. W. A. Betts. A selection of the writings of Osler on medical education was displayed, together with many messages which had been received from friends and corresponding members of the club abroad. Among those present were Sir D'Arcy Power, Sir William Hale-White, Sir F. G. Kenyon, Dr. Andrew Balfour, Mr. Hugh Cairns, Mr. Philip Franklin, Dr. Marshall Fulton, Mr. R. H. Hill, Dr. N. G. Horner, Mr. E. Muirhead Little, Dr. J. D. Rolleston, and Mr. Paterson Ross.

Scotland.

Health of Glasgow.

THE annual report for 1928 of the medical officer of health for Glasgow (Dr. A. S. M. Macgregor) was issued on July 8th. The population of the city is estimated at 1,147,103, and its density as 39 persons per acre. The births registered during the year numbered 23,649, giving a rate of 20.62 per 1,000—the lowest on record. The corresponding rate for Edinburgh, reported in the *British Medical Journal* of July 13th (p. 71), was 17.3. The birth rate varied from 28.6 in the industrial ward of Mile End to 7.9 in Kelvinside. The total number of deaths was 16,727, representing a rate of 13.7 per 1,000, which is the same as in Edinburgh. The infantile mortality rate was similar to that of the previous year—107 per 1,000. Dr. Macgregor points out that this figure, which is higher than that of most other large towns, cannot be regarded as satisfactory. About 36 per cent. of these deaths occurred in the first month of life. The maternal mortality rate of 8.79 per 1,000 births was higher than in the preceding two years. The rate for infectious diseases was greater than in 1927, principally because of the larger number of fatal cases of measles. The serious problem constituted by measles, whooping-cough, and acute pneumonia, all of which destroy life by attacking the lungs, is commented upon. The figures for tuberculosis are much the same as in the previous year. There were 1,247 deaths from malignant disease, a reduction of 81. Dealing with housing, the report refers to the fact that 6,895 houses were granted by the Dean of Guild Court for new dwellings, which is the highest figure for more than half a century; 60 per cent. of the new houses were of three apartments. The custom of subletting a room, mostly in houses of two apartments, which has been a feature of recent years owing to the housing shortage and unemployment, is still very prevalent. Although the housing schemes are now affording a definite measure of relief, there is still a large volume of overcrowding in the city. About 80 per cent. of the tenants in the new housing areas have proved satisfactory so far as cleanliness is concerned.

The number of persons who default from attendance for treatment at the Glasgow venereal disease clinics is still large enough to be disquieting. Dr. Macgregor attributes this failure to attend largely to ignorance and indifference. The nurse almoner appointed to visit defaulters has made more visits than ever, but personal persuasion alone appears quite inadequate to secure continued attendance. Dr. Macgregor records his opinion that the voluntary system of treatment of venereal disease without official notification and without the application of any special powers of compulsory treatment is still on its trial; most of the efforts to deal with the problem of venereal disease, he continues, are still in the experimental stage. Dr. Macgregor finds it difficult to decide whether there has been an increase of venereal disease or not; it might be argued, he thinks, that propaganda among the public and instruction given to patients at clinics are causing a diminution of venereal disease, and that the increased numbers attending the clinics, and the increased aggregate attendances, only mean that cases which hitherto would have been undiscovered are now coming for, and accepting, treatment to a fuller extent than formerly. Treatment of venereal disease is carried out at six of the thirteen maternity and child welfare centres. As the diagnosis of syphilis in the pregnant woman is not always easy, it is becoming more and more the practice in Glasgow to take blood for the Wassermann test from every pregnant woman attending the municipal ante-natal clinics; of 584 pregnant women so examined 29 were found to be infected with syphilis.

Glasgow is the only area in the United Kingdom in which trachoma is a notifiable disease. A trachoma dispensary and a special trachoma nurse are provided; cases requiring in-patient treatment are admitted to the special ward in Ruchill Hospital. Of 127 cases on the register 111 were born in these islands; the age group 15 to 20 yielded the largest number of new cases. The disease does not spread much in the home; an examination of the home contacts of 33 cases notified in 1928 yielded only one case of definite trachoma; in only five instances are there multiple cases in a family. There were 36 new applicants during the year for insulin, which is given to persons not already provided for under the national insurance scheme or the Poor Law. The report provides support for the view that scarlet fever may take the form of sore throat. Groupings of scarlet fever and sore throat occurred in two schools. In one, a county school on the city boundary, three cases of definite scarlet fever were followed by a series of thirteen cases of sore throat, occurring at short intervals, and by a fourth case of scarlet fever. In ten of the sore throat cases the tongue was generally coated, but definite peeling occurred only in three; in no case was there any trace of desquamation. Examination of throat swabs showed the presence of haemolytic streptococci in ten out of the thirteen cases. No other case of scarlet fever was present in the district to infect the fourth case; also, for six months after the last case of sore throat there was no further absenteeism due either to scarlet fever or to sore throat. The need for international hygiene is shown by the bacteriological examination of goat-skin thongs used to bind orange boxes. Nine out of fifty-two tests revealed the presence of anthrax bacilli. Dr. R. M. Buchanan, bacteriologist to the corporation of Glasgow, states that since the inception of these examinations certain places have stood out conspicuously as sources from which infected thongs have been derived.

Finances of Edinburgh University.

A memorandum on the finances of Edinburgh University was read at a recent meeting of the University Court. The ordinary revenue had increased from £110,000 in 1913-14, the last pre-war year, to £250,000 in 1927-28. In these figures no account is taken of scholarships and bursaries, in respect of which the University is only a trustee. Of the whole regular income, about £48,000 comes as interest from endowments; £91,800 as parliamentary grants (made up of £10,800 granted under the Local Taxation (Scotland) Act of 1892, and £81,000 from the University Grants Committee); and £107,000 in fees. No form of rate aid is received, as is the case with most of the English universities. As regards ordinary expenditure, the salaries of the teaching staff, amounting to £141,000, constitute the heaviest item. Pensions and superannuation contributions account for £15,000, departmental expenses for £25,000, libraries and museums for £9,000. The cost of administration, including the salaries of the principal and of members of the secretarial staff, is about £18,000. There is a charge of £30,000 for maintenance of premises, and an item of £10,000 for incidental alterations and adaptations of buildings apart from any large schemes of university development, the costs of which are met by means of special gifts. The whole expenditure charged to the ordinary account for 1927-28 was £253,000, leaving a deficit on the year's working of £3,500. The second part of the memorandum dealt with bequests and gifts which had been received during the thirteen years of Sir Alfred Ewing's principalship. These were as follows: bequests, £291,018; gifts from private persons, £298,030; gifts from public bodies, including £198,000 from the Rockefeller Foundation, £316,494; grants from the Carnegie Trust, £202,000; and non-recurrent grants for capital purposes from the University Grants Committee, £67,153; making a grand total of £1,174,695. Of this sum of over a million pounds, fully one-half has been invested to provide endowments, while the remainder has been or is being applied to various extensions.

Extension of Lewis Hospital.

On July 5th Mrs. Macaulay formally opened, at the Lewis Hospital, Stornoway, a new wing, consisting of two maternity wards with nurses' accommodation, the gift of her husband, Mr. T. B. Macaulay, president of the Sun Life Assurance Company of Canada. Mr. Macaulay, to whom reference was made in our issue of July 13th (p. 71) in connexion with his gift to the Aberdeen Institute of Soil Research, was born in Aberdeenshire, but his forebears came from the Island of Lewis, and he has taken an active interest in all that pertains to the welfare of the island. Provost Bain, chairman of the hospital managers, who

presided, explained that, in addition to presenting the new wing, Mr. Macaulay had endowed the hospital to the extent of £16,000, besides setting aside a further sum of £1,500, which will ultimately come to the hospital. Mr. Macaulay, in the course of an address, said that it gave him great pleasure and satisfaction to be able to contribute to the good of the people of the island, but he was anxious that the hospital should not be so well endowed that there should remain little or no incentive for the people themselves to support it. He had, however, been assured that there was no ground for such a fear. His feeling was that the hospital was not yet large enough for the needs of a population of 32,000 persons, and that still further extensions would be necessary. It was later intimated that another gift of £3,000 towards the endowment fund had been received from Mr. John Bain of Chicago, a brother of the Provost of Stornoway.

New Chair of Botany at St. Andrews.

By a recent ordinance a chair of botany has been established in St. Andrews University, and the departments of botany in the United College of St. Andrews and in University College, Dundee, are to be placed under the charge of the new professor. The lectureship in botany in Dundee and the assistant lectureship in the United College, at present existing, are continued under the new arrangement. The council of University College, Dundee having concurred in the appointment, the University Court has elected Mr. R. A. Robertson, M.A., B.Sc., to be the first professor of botany, as from October 1st next. Mr. Robertson was lecturer in botany in the United College, St. Andrews, from 1891 to 1915, and has been reader in botany in the same department since that year. Mr. Robertson's long and valuable services to the University in many capacities are highly appreciated by the Court and by the Senatus, of which he became an elected member in 1924.

Correspondence.

A PHYSIOLOGICAL STUDY OF ASTHMA.

SIR,—You have rendered a service to all those interested in the physiology and pathology of spasmodic asthma by issuing an abstract (July 13th, p. 68) of the valuable paper by the late Professor T. G. Brodie and Professor W. E. Dixon on the pathology of this affection (published in 1903).

The authors devote a considerable proportion of their paper to the over-distension of the chest observable during the asthmatic paroxysm. They state—I quote from the abstract—that during the over-distension accompanying an asthmatic attack, inspiration is much more powerful than expiration. "It is a matter of observation, which has not been nearly sufficiently stressed by authors of textbooks, that the effort, during an asthmatic attack, is an inspiratory one; expiration is quiet and prolonged. The patient's efforts are directed to getting air into the lungs, not to getting it out. In most instances the description is that *respiration* is violent; it should be that *inspiration* is violent."

All this is perfectly true. How are we to explain this curious type of breathing—the comparatively short, violent inspirations followed by the longer, less vigorous expirations, a sequence speedily resulting in superdistension of the lungs? The authors state that the chest is necessarily over-distended during an asthmatic attack, "for the constriction of the bronchioles tells far more heavily against expiration than inspiration." I have to confess that I do not understand why it should, but I defer on this point to their wider knowledge; what I desire to emphasize is a truth which seems very generally to have been overlooked, although I have myself more than once drawn attention to it—namely, that in all ordinary cases of dyspnoea, such as result from physiological causes, or from heart or lung disease, the mean size of the lungs tends to undergo a compensatory increase. This increase is effected by powerful inspirations followed by less powerful expirations, the expansions and contractions of the chest taking place about an increased mean; were the expiratory muscles to act as powerfully as the inspiratory, the range of the respiratory movements would be greatly amplified, but the *mean size of the chest would not be increased*. This type of breathing is well illustrated in physiological dyspnoea, such as is produced by running rapidly up several flights of stairs. At the end the chest will be found to be expanded, inspirations being short and powerful, while expirations are effected by little more than the elastic recoil of the lungs and ribs. Manifestly the purpose of this type of breathing is to increase the *mean* respiratory area and to facilitate the flow of blood from the right to the left heart. The same type of breathing, leading to pulmonary expansion, is observed in the dyspnoea of heart and lung disease, and with the same object—to increase the mean respiratory area (note that the mean would not be increased if expirations were deep), and to facilitate the pulmonary flow. An additional reason for expansion in heart disease is the considerable encroachment which a greatly enlarged heart makes upon the pulmonary area. A similar type of breathing with expanded chest is observed in the dyspnoea of elderly obese persons.

One of the most interesting forms of dyspnoeic expansion is that which occurs in so-called hypertrophous emphysema, the pathology of which is as simple as it is interesting. In ordinary circumstances nearly the whole of the pulmonary tissue is kept in a condition of moderate tautness (elastic tension). It is the business of the inspiratory muscles to maintain this tautness at the right degree, so that the walls of the expanding and contracting alveoli shall always be stretched and not allowed to become wrinkled and encroach upon the alveolar cavities, thus seriously interfering with the aeration of the blood (as happens at the end of an extraordinary expiration).

With advancing years the elasticity (capacity of recoil after being stretched) of the lungs lessens like that of the skin, and tends to produce a wrinkling of the alveolar walls, and thus greatly to curtail the respiratory area of the lungs. To prevent this the inspiratory muscles, ever on the watch to maintain the alveolar walls at their normal degree of (rhythmically waxing and waning) tautness, come into extra play and tighten up the elastic fibres to the requisite degree, just as one would tighten up a violin string which had become too lax. In this way the overacting inspiratory muscles bring about a gradual increase in the size of the chest. In consequence, the inspiratory muscles of the neck shorten (just as happens in the case of the overacting muscles in the different forms of talipes), causing the shoulders to be raised and the neck to shorten, the curvature of the ribs becomes permanently altered, the costo-vertebral joints and ligaments undergo adaptive changes, and eventually we have the typical barrel-shaped chest fixed in a position of super-extraordinary inspiration.

Such, as it seems to me, is the essential pathology of hypertrophous emphysema, which, by the way, may occur independently of asthma or dyspnoea, and may have advanced considerably before any rupture of the pulmonary alveoli has taken place. The expansion of the chest in this affection is manifestly compensatory; were the chest of a patient in an advanced case of emphysema reduced to the normal dimensions of early adult life, death from suffocation would result in a few minutes.

The same tendency to thoracic expansion may be seen in advanced pulmonary tuberculosis, when a struggle takes place between the scar tissue of the adherent lungs (tending to pull the ribs inwards and to produce flattening), and the powerfully contracting inspiratory muscles (tending to pull the ribs outwards). The expanding forces may lead to such a degree of expansion of old cavities, such a degree of dilatation of the bronchi, and such stretching of the pulmonary alveoli, as to cause an actual deepening of the chest, as may be seen by observing the chest in profile.

I come now to the rationale of the breathing and of the expanded chest observed in spasmodic asthma. I suggest that the chest expands in this affection in accordance with the principles I have enunciated: the expansion is, I suggest, a compensatory measure—a physiological effort to make the best of a bad job. A chest expanded to the maximum maximizes the respiratory area and minimizes the resistance to the pulmonary flow from the right to the

left heart. Further, the air conduits between the bronchi and the alveoli are far more likely to be kept open when the chest is fully expanded—that is, when these conduits are tugged upon from without by tissues stretched to an extra degree of tautness—than when these tissues are in a condition of average tautness. My impression is that the asthmatic is instinctively led to act during the attack in a way best calculated to cope with the situation. He makes mighty inspiratory efforts to get air into his chest, but he *dare not* expire deeply, and has to be content with cautious, inadequate expirations, through fear of completely occluding the minute air conduits. Expiration beyond a certain degree would tend to have this effect, and the asthmatic is careful to cease to expire before that contingency arises, for we must remember that the respiratory interchange between the bronchioles and the alveoli takes place mainly by transfusion—there is little air current between them—and hence aeration takes place during expiration as well as during inspiration.

I have said that in dyspnoea, whether physiological or pathological, the chest tends to expand through overaction of the inspiratory muscles. In all cases of heart and lung disease, in which dyspnoea is urgent, the inspiratory muscles of the neck can be felt, and often seen, to be acting powerfully. Normally the sterno-mastoids only come into action towards the end of inspiration. When these muscles stand out in a state of chronic tonic contraction we may draw the certain conclusion that the chest is expanded beyond the normal mean size.—I am, etc.,

London, July 15th. HARRY CAMPBELL.

ABDOMINAL SEPSIS AS A CAUSE OF EYE DISEASE.

SIR,—Professor Wilkie's article, "The gall-bladder in relation to focal infection" (July 13th, p. 37) should be of great interest to ophthalmic surgeons. For many years I have regarded the gall-bladder as a source of infection of the eye, and when trying to find the septic focus in a case of cyclitis or other ocular inflammation it is my practice to ask a general surgeon to examine the case, when, often an *x*-ray examination is made of the gall-bladder and cholecystitis diagnosed.

There is a low-grade optic neuritis which can generally be traced to some variety of abdominal sepsis; in fact, I speak of the "abdominal eye" to my students. The edges of the disc are slightly blurred, the surface is slimy-looking, the vessels have sheaths, and there is a general hyperaemic appearance. In such cases I have suggested to the patient that she is suffering from some abdominal disorder, and have often found that my guess is correct. One woman said, "Oh yes, I had my appendix out a month ago."

Cholecystitis is, I think, the commonest abdominal cause of this condition, and should never be neglected in any case of inflammation of the eye. In the Coventry Hospital I have no difficulty in making these investigations. The patient is admitted to my ward: one of the general surgeons attached to the hospital examines her, and if the gall-bladder is diseased the patient is transferred to the surgical wards and the gall-bladder is removed. In a special eye hospital it is not so easy, because the patient has to be sent to a general hospital and may be lost sight of.—I am, etc.,

Birmingham, July 15th. T. HARRISON BUTLER.

IMPACTED CYST IN THIRD VENTRICLE OF BRAIN.

SIR,—In his interesting account of two fatal cases of impacted cyst in the third ventricle, published in the *British Medical Journal* of July 13th (p. 47), Professor A. M. Drennan mentions the rarity of records of similar cases.

In 1913 I was able to find records of nine similar cases, including two under my own care, the specimens from which were shown at a meeting of the Pathological Section of the Royal Society of Medicine in 1911. Those two cases were recorded in full in the *Lancet* of January 11th, 1913, under the title "Two cases of colloid tumour of the third ventricle causing death." The histories and the appearances (both naked-eye and histological) of the nine cases recorded up to 1913 correspond so closely with those described by Dr. Drennan that there can be no doubt they have the same etiology. Thus one of my patients was a young woman who had suffered for a few months from intermittent attacks of severe headache, thought to be merely "migraine"; after she had been lying down for a few hours they would pass off. One day she stayed in bed on account of an attack, and later in the day was found there dead. At the necropsy there was found extreme distension of the lateral ventricles due to a small globular cyst of the choroid plexus plugging the foramen of Monro. In my second case a man was found lying unconscious in the street; he died soon after admission to hospital. Nothing was known of his previous history. At the necropsy an exactly similar condition was found—a small globular cyst of the choroid plexus plugging the foramen of Monro. In neither instance was there any evidence of disease elsewhere.

There are few sites in the body where so small a mass can produce death solely by its mechanical effects, and few conditions in which a fatal result can follow such an extremely localized lesion. The actual size of these colloid cysts of the third ventricle is usually somewhat less than that of a child's "toy marble." In character they are innocent, and their effect is purely mechanical. As a rule they are discovered in young adults, in whom no other lesion is found at necropsy. Death is due solely to obstruction of the anterior end of the third ventricle at the foramen of Monro, where the streams of cerebro-spinal fluid from the two lateral ventricles converge and pass into the third ventricle.

That such a series of events leading to death occurs in these cases is a confirmation of the truth of our physiological views on the cerebro-spinal circulation. No doubt each attack of headache represented some slight change of position of the cyst causing a temporary and partial obstruction. This was relieved possibly by a change of position of the cyst on the patient lying down, or by some alteration in the relative pressures, so that the temporary obstruction was relieved. As the cyst enlarged, however, the time arrived when it became wedged; the resulting increase of pressure which this caused in the lateral ventricles simply added more and more to its immobility, and recovery was impossible.—I am, etc.,

Sheffield, July 15th. ARTHUR J. HALL.

SIR,—Professor Drennan describes in your columns two cases of "rapid death," in both of which the fatal termination was determined by a cyst, growing from the choroid plexus, which had become impacted in the foramen of Monro, with consequent acute hydrocephalus and oedema of the brain.

I recall two cases in which death was due to this most unusual accident. One of these, which was observed by Sir Farquhar Buzzard and myself during life, is briefly reported, and figured in another context, by the late Dr. F. E. Batten and Dr. James Collier in their paper on "Spinal cord changes in cases of cerebral tumour" (*Brain*, vol. xxii, 1899, p. 532). The second case is described, with an illustration of the brain, by the late Sir Thomas Fraser in a communication entitled "A case of complete transposition of the viscera with cerebral tumour and other pathological conditions" (*Trans. Med.-Chir. Soc. Edin.*, vol. xxiii, New Series, 1903–4, p. 233). A third instance is recorded by Dr. T. H. Weisenburg in his paper on "Tumours of the third ventricle" (*Brain*, vol. xxxiii, 1910, p. 243).

This mode of death has not hitherto, so far as I am aware, been specially referred to in the literature, hence the reason for this note.

The cyst in one of Professor Drennan's cases was only "the size of a large pea," and the lateral ventricles were but "slightly dilated"; it is indeed not improbable that in some cases of the kind death may have been attributed to an oedema of the brain of undetermined etiology.—I am, etc.,

Edinburgh, July 13th. EDWIN BRAMWELL.

IMMUNIZATION BY TUBERCULIN.

SIR,—"The method of stamping out tuberculosis is to immunize children of tuberculous parents and to produce active immunity in early cases of tuberculous infection" (Dr. Nathan Raw, May 25th, p. 951). Nothing could be more admirably succinct than this statement, which Dr. Manning justly comments upon as opening up "a subject of enthralling interest" (June 22nd, p. 1142). Where conviction fails is, not in the presentation of the case, but in the details of procedure by which it is proposed to attain the object.

Will Dr. Nathan Raw's two injections of attenuated tubercle bacilli (June 29th, p. 1180), or even his six such injections in doses of from 0.001 mg. to 0.006 mg. at weekly intervals, repeated in three months (April 23rd, 1921, p. 596), confer sufficient immunity to be of practical value? Will his twelve such injections from 0.001 mg. to a maximum of 0.025 mg. go very far towards the cure of those already infected? The problem in both cases is, I fear, much more difficult than Dr. Nathan Raw would have us believe, and the evidence which he has hitherto produced from animal experiments and otherwise does not appear to me to be at all convincing. Dr. Nathan Raw himself does not appear to expect very much from specific curative procedures, judging from his quotation from Metchnikoff: "The results," he quotes, "amount practically to nothing," and, he goes on to say, "we have reluctantly to admit that we are in much the same position to-day" (June 29th, p. 1180). Again, will Dr. Manning's judicious pushing of P.T.O. up to P.T. (June 22nd, p. 1142) "stem and finally oust the disease" in those who are already infected? Although we are here on somewhat firmer ground, I am not aware of any evidence which gives the use of P.T.O. or P.T. as described by Dr. Manning a title to preference over B.E. or T.R. as used in accordance with the directions of Koch in force at the time of his death.

This is the whole case in a nutshell. In the material presented in these communications sufficient proof is wanting to carry conviction. As soon as that is forthcoming, and not before, will the case for initial immunization, both protective and remedial, be accepted and the stage of simplification of procedure entered upon. It is necessary to proceed with the greatest caution in these fundamental conceptions, and to prove each part of the argument beyond the possibility of doubt or error.

Like Dr. Manning, I think that sufficient evidence has not been produced by Dr. Nathan Raw to prove that his tuberculin from attenuated cultures possesses any advantage over Koch's B.E. or T.R. properly diluted and skilfully used, and the evidence in support of Dr. Nathan Raw's immunizing procedure is, to my mind, quite insufficient upon which to found a clinical scheme. I think I may say, judging from experience of the administration of B.E. in doses of many milligrams, repeated over long periods, that Dr. Nathan Raw's specific methods will not do much to arrest the disease when present, and I fear that his two minute doses of killed attenuated cultures likewise will not go far in the direction of prophylactic immunization.

On the other hand, there is sufficient evidence in the literature of the subject to corroborate Koch's claims as to the reliability and harmlessness of his subcutaneous tuberculin test as a proof of the presence or absence of tuberculous infection, and there is also evidence to support his claim that B.E. or T.R., administered in accordance with his instructions, will cure incipient infection with certainty. Success with tuberculin seems to depend inversely upon the amount and severity of infection, as might have been anticipated. We have therefore, as Dr. Manning clearly foreshadows, already in our hands a practicable scheme for the complete elimination of tuberculosis. Test all children who conform to Koch's criteria of suitability for the test, by Koch's subcutaneous tuberculin test, treat the reactors *by every available method*, including Koch's specific treatment by B.E. or T.R., until they become permanently negative, and pass them into a tuberculosis-free group, and tuberculosis will have become a thing of the past within one generation. Three years ago I described in detail in your pages (October 16th, 1926, p. 662) three cases of changed reaction to tuberculin from positive to negative, illustrating this procedure, and I have just successfully completed a still more illustrative case in a girl of 14 with a parallel negative control case. The difficulty at present lies in the lack of general acceptance of such views—"it is a controversial subject"—and in the tedious nature of the process.

The argument quoted at the beginning of this letter is a definite landmark in the anti-tuberculosis campaign and a prophecy of victory. It is an urgent necessity in the interests of all who are infected, or destined to become infected, with tuberculosis, that the fundamental conceptions of Koch should be examined and re-examined and proved and proved again, till the facts are placed altogether beyond the range of controversy. The present position is very much as Koch left it and as Koch envisaged it, and the time is opportune for a reaffirmation and, what is more important, a re-examination of his claims, now that attention has been caught and focused upon the salient points. The lamentably slow progress of investigation of his important claims is a reproach to medicine. Surely the crucifixion of the human race by this particular disease has lasted long enough.—I am, etc.,

London, S.W.18, July 5th. ROBERT CARSWELL.

BREAST-FEEDING BY TUBERCULOUS MOTHERS.

SIR,—I have been re-reading Dr. Bernard Schlesinger's admirable article on "Tuberculosis in childhood" (April 27th, p. 759) and there is one small sentence to which I would like to call attention. He says, "tuberculous mothers should not breast-feed their babies." In a fairly extensive reading of the literature of tuberculosis I have come across but one authority—Dr. Joseph Walsh of Philadelphia—to disagree with the above teaching, and as I think his views are at least worthy of discussion, I give them, as far as I can, from hasty notes taken at the time. He stated some years ago in an American medical journal that "with a tuberculous mother, it is a question of the bottle or the mother's milk. Most physicians decide for the bottle, with the idea of conserving the mother's energy and lessening the risk of infecting the baby. Personally, I think if the circumstances of the family are such that the mother must care for the baby, it is more satisfactory for her to nurse it, for if the baby is brought up on the bottle it will almost surely be ill; if on the breast it will almost surely be well. It seems to me to be less waste of energy for a mother to nurse a well baby from her own breast than an ill baby artificially. In regards to infection, there appears to be little or no danger of transferring tubercle bacilli by the milk, and in relation to handling, I think the mother is just as likely to infect the nipples of the bottle as of her breast."

In my own work, if the mother is my main consideration, I am guided by the particular circumstances of the case, but if I am more concerned with the baby, I have mostly followed Walsh's teaching, and I think I have been justified by the results.—I am, etc.,

P. J. BURKE, L.R.C.P., D.P.H.,
Sligo, June 30th. County Tuberculosis Officer.

THROMBO-ANGIITIS OBLITERANS.

SIR,—In your account of the discussion on diseases of the Jewish race, on June 13th, at the London Jewish Hospital Medical Society (*Journal*, July 13th, p. 51), I am reported as saying that in my opinion thrombo-angiitis obliterans was a disease with an economic rather than a racial basis. May I be allowed to correct this, and at the same time to make some remarks on the subject?

I certainly did say that some of the Jewish patients had had hardships to pass through in their early life—imperfect nourishment, perhaps, qualitatively or quantitatively, in some cases—and that the affected individuals were nearly all of the poorer classes, as were also the subjects of the disease in China and Japan. What, however, I chiefly urged was that there was a constitutional basis of some kind which favoured the development of the disease, and which seemed not to be specially connected with the endocrine glands. Though there was hardly any evidence of the familial incidence of thrombo-angiitis obliterans,

there were sometimes grave constitutional defects in other members of the patient's family (for example, grave diabetes mellitus in two children of one of my patients and Raynaud's *syndrome* in the baby grandchild of the same patient).

I would here suggest that the constitutional congenital-developmental factor in question may be of the nature of a primary defect in the walls of the blood vessels of the limbs, sometimes manifested by definite hypoplasia. Indeed, in cases of intermittent claudication in one or both legs in early middle life (whether in Hebrews or others), when thrombo-angiitis obliterans is suspected to be the cause, it is sometimes difficult to be sure that the symptoms are not entirely the result of arterial hypoplasia without any actual arteritis.

The lower limbs may be chiefly affected because, as a rule, they are subjected to more muscular strain than the upper ones: if nicotine is an exciting cause, it should be remembered that more nicotine must pass through the blood vessels of the parts that are most functionally exercised. The immunity of females may be partly explained by the abuse of nicotine having been as yet very rare or non-existent amongst Hebrew women of the poorer classes, and possibly by there having been less muscular exercise involving the lower limbs. But there may also be some other unknown factor to account for the sex-immunity, which appears to be almost as remarkable as in haemophilia.

All this *does not prove that thrombo-angiitis obliterans* may not be the result of a non-suppurative "low-grade" infection, for a low-grade infection may be dependent on a constitutional defect (for instance, some cases of chronic osteo-arthritis?). Indeed, in some cases the "matting" of the tissue around the affected blood vessels is suggestive of a low-grade infective process, and (by involvement of the peri-arterial nerve plexus) partly explains the frequency of associated erythromelalgia-like symptoms. An almost equally strong argument in favour of a microbic factor in the etiology of thrombo-angiitis obliterans is the occasional (though very exceptional) gradual dying-out of the disease after repeated exacerbations. This has occurred in the case of a man first seen by me in 1906 and still under my observation.[1]—I am, etc.,

London, W., July 13th. F. PARKES WEBER.

GAS-OXYGEN ANAESTHESIA.

SIR,—I cannot leave unchallenged certain statements made by Dr. E. J. Chambers on July 13th (p. 74).

It is not so rare "to come across any student who has been taught gas-oxygen anaesthesia." Most, if not all, students at St. Bartholomew's are instructed by means of Boyle's apparatus, which is to be found now at most *teaching hospitals*. At the Middlesex Hospital anaesthetic clerks are taught, not by the "semi-open ether or C.E." method, but by Hewitt's gas-ether inhaler followed by open ether.

The next misapprehension is that "the control of the gases is so erratic." By means of Adam's reducing valve the gases flow at a remarkably steady and easily controllable rate, even at the end of long operations. An "emergency" oxygen valve is not essential, it only being necessary to shut off the nitrous oxide or ethylene, and to increase the oxygen flow, remembering always to have a safety valve attached to the apparatus. Artificial inflation of the lungs under positive pressure is considered inadvisable by many anaesthetists, for fear of rupturing the pulmonary alveoli or of causing cardiac embarrassment.

Finally, in answer to Dr. Chambers's third generalization, it should be apparent that no man who gives any form of anaesthesia can afford to go to sleep on the job.—I am, etc.,

Chelmsford, July 13th E. V. SLAUGHTER.

RELATIONSHIP OF ALASTRIM (VARIOLA MINOR) TO SMALL-POX (VARIOLA MAJOR).

SIR,—I thank Dr. Killick Millard for his courteous letter published in the *Journal* of June 15th (p. 1099). My delay in replying is due to the fact that I had mislaid the copy of *Nature* dealing with the inheritability of acquired characters.

I was, however, fortunate to-day in finding in *Nature* of June 29th (p. 930) a letter by Professor MacBride, in which, under the heading of "The Origin of Adaptations," he states as follows: "Since that time Metalnikoff, of the Pasteur Institute in Paris, has proved the inheritability of acquired immunity in the caterpillars of the beeswax moth; and this experiment is doubly interesting, because the effect on the offspring of the acquired character only became obvious after five generations, incidentally confirming Lamarck's view, who rightly emphasized the importance of the time factor in use-inheritance."

I do not find myself in agreement with Dr. Killick Millard in his belief that the immunity of native races to malaria is due to natural selection, and I think the time is now ripe for a general review of the whole question of the so-called natural immunity.—I am, etc.,

Little Island, County Cork, July 11th. E. G. FENTON.

SIR,—Correspondence at a distance of 6,000 miles, with consequent interval of about eight weeks between letters, is unsatisfactory; but I cannot allow the arrogant and discourteous letter (May 18th, p. 927) from Dr. Millard to pass. I am quite aware that I am a mere general practitioner, while he would appear to be among those whom he styles "experts"; but with thirty years of practice behind me I am certainly not going to swallow humbly such a farrago of assumption as Dr. Millard would have me accept. The date of the case in question was 1920. Deeming the actual year to be a detail of no moment, I referred to it as occurring some years ago. These words Dr. Millard puts in inverted commas. Why he should do so I fail to understand, unless his idea was to query the case having occurred at all. Then he styles my term "mild small-pox" a most unscientific name. I should like to know why. Is it because it is in plain English and not camouflaged in Latin or Greek? A scientific term should convey to the reader exactly what it means. When one writes "mild small-pox" not only 99½ per cent. of medical men, but 100 per cent. of laymen know what is meant. If one writes "variola minor" not even the expert knows, according to Dr. Millard. From the days of Hippocrates and earlier there has been held up to ridicule in plays and books the pompous creature who covers his ignorance in a flood of long and unmeaning words.

Dr. Millard complains of my settling the *crucial point in* such a "facile manner," while he himself assumes the whole question to be as he sees it. He accuses me of failing to appreciate the difference between clinical type and strain or variety. When he or any other expert can demonstrate, *without room for doubt or cavil*, that there exist *different* strains of small-pox, I shall be delighted to accept the position; but mere assertion is not proof. Nor is the record of strings of cases proof. In other diseases, as measles and scarlatina, one sees epidemics of very mild cases and *epidemics of very severe cases*. Possibly these are also different strains, but so far that has not been demonstrated. He says that there is no practical difference between his strains, that a mild (here quite a scientific term) case of "variola major" may be indistinguishable from a severe case of "variola minor." (The only difference, according to evidence to date, exists in paper and expert assumption.) He says that the only way to distinguish them is to allow them to propagate other cases and see whether they produce similar cases. Well, supposing my culminating case, the severest of the series, had propagated similar severe confluent cases, would that have elevated it to the rank of major? Unfortunately an unscientific Government sent me to that farm to put an end to the "small-pox"—they did not even mention "variola"—and I promptly and without a thought for "science" did as they asked.

Dr. Millard mentions a similar case to mine of severe confluent small-pox occurring in an outbreak of "undoubted variola minor," and says that even if it had been fatal there would still have been no question of its being a case of "variola major." He seems to have settled the matter to his own satisfaction—to use his own expression, in a facile manner, that of dogmatic assertion—but of proof under the microscope or on a plate he adduces not a scintilla

[1] F. Parkes Weber *Proc. Roy. Soc. Med.*, Clinical Section, 1925, xviii, p. 38.

Such mere assumption of things, however dogmatically and expertly asserted, does not amount to scientific, not even to ordinary, proof.—I am, etc.,

JOHN A. GRAHAM, M.B., C.M.

Bethulie, South Africa, June 24th.

APPENDICITIS CAUSED BY BILHARZIA.

SIR,—Under this heading in your issue of May 4th (p. 810) Dr. H. Elwin Harris, jun., records an interesting case, but gives as his reason for bringing it forward that in the records of bilharzial lesions he has been unable to find any instance of appendicitis caused by this parasite.

He has overlooked a communication entitled "Bilharzial appendicitis," which I published in the *Transactions* of the Royal Society of Tropical Medicine and Hygiene, vol. xviii, 1924, p. 210, in which I recorded twenty cases occurring during the years 1919–23. These came under my notice in carrying out routine examinations of specimens sent to the South African Institute for Medical Research, for histological report. These were all specimens removed at operation, and in all but one the ova and structural changes due to them appeared to be the sole lesion present, and were presumably, therefore, the cause of the symptoms which had led to appendicectomy being performed. In the one exception there was a haemorrhagic, almost gangrenous, inflammation, obviously an acute condition complicating the chronic bilharzial lesion. Several other cases from literature were also referred to in this communication.

I might add that bilharzial appendicitis is now fairly commonly recognized in South Africa, and during the five years 1924–28 some 31 further appendices removed at operation have been reported on at the Institute as bilharzial—10 of these by Dr. A. Sutherland Strachan and 21 by Dr. F. W. Simson. Reference is being made to these in the annual report of the Institute for 1928, now in the press.—I am, etc.,

Johannesburg, June 10th. J. H. HARVEY PIRIE.

SPA TREATMENT.

SIR,—In the *Journal* of June 22nd (p. 1141) I suggested that it would be helpful if members of the Spa Practitioners Group would think over the wording of a definition of a spa and spa treatment before the forthcoming Annual Meeting in Manchester, and at the same time I put forward a definition, which I still think includes the essential points. In the *Journal* of June 29th (p. 1181) Dr. Collis Hallowes says he thinks the definition cumbersome and unlikely to meet with general approval, but does not offer any suggestions for its improvement. He asks, "What is the necessity at the present time for a definition of forms of treatment which are difficult to define when the word 'spa' is attached to them?" I think the mere fact of the formation of the Spa Practitioners Group is evidence of this necessity.

It is difficult to define a spa practitioner without defining spa treatment, or to define spa treatment without defining spa waters. Now, while medical men may hold widely different views as to the comparative therapeutic value of spa waters and "tap water," the corporations, or similar bodies, owning the spa waters, are quite unanimous about their money value, and jealously guard their proprietary rights. Any medical man may give a patient a prescription to drink or bathe in these waters, and in fact there is nothing to prevent any person willing to pay for them from drinking and bathing without a prescription. The spa authorities, from the mere business point of view, would probably prefer to employ whole-time medical men to administer their waters and treatments, but on the whole work amicably with the spa doctors, realizing that their individual reputations, and skill in the use of their waters and baths, are assets in attracting patients and custom to the spas.

What, then, was the need for the formation of the Spa Practitioners Group? Briefly, the proposal to make spa treatment an additional benefit under the National Insurance Act, not necessarily for the treatment of the rheumatic group of diseases only. The three bodies most nearly concerned were the large approved societies, the spa authorities represented by the British Spa Federation, and the spa doctors. The spa doctors alone had no representative organization. They were situated mainly in some dozen spas, and were collectively but a small number. They agreed that the British Medical Association was the proper body to represent them in negotiations with the Ministry of Health, the Approved Societies, and the Spa Federation. As a whole, the spa doctors welcomed the proposed spa treatment of insured patients. They realized that a well-organized scheme would be a great advantage to the spas, as well as to the patients, but that inadequate arrangements would be a great waste of public money and most harmful to the reputation of the spas. Individually they realized that, whether they gave their personal services to the scheme or not, it would affect their personal interests, as administrative changes in a spa affect the work of all the local spa practitioners.

The first step was to agree upon terms of membership of the Spa Practitioners Group, which are approximately as follows: Members shall be regularly engaged in prescribing the baths and waters of the spa in which they reside, *or*, shall be on the staff of an institution or clinic where the use of the local spa waters forms part of the routine treatment. The spa doctors who first discussed this matter wished to make the terms of membership such that they would include every qualified medical man actively engaged in spa practice who was willing to join; but for the group to be of any real use to its members it was essential that there should be a clear differentiation between those medical men practising as spa doctors and those using other forms of physiotherapy—hydrotherapy, electrotherapy, etc.—independently of spa authorities. This was the only means by which they could safeguard themselves from being outvoted on matters specially pertaining to spa practice.

I trust that the foregoing remarks will make it clear that my attempts to define spa treatment and to differentiate it from other forms of physiotherapy have not been deliberately "contentious," or in any way calculated to belittle other forms of treatment.

In the *Journal* of July 6th (p. 31) Dr. Fortescue Fox, referring to the comments of Dr. Collis Hallowes, writes, "A name may have unlooked-for effects, especially when it becomes a more or less exclusive label for a society or group of medical men." I think I have already made it clear that the terms of membership of the Spa Practitioners Group were as *inclusive* as possible. Dr. Fortescue Fox continues, "For practical purposes it is better, if possible, to find a name that will unite in one group all who study different parts of the same subject." I agree with Dr. Fortescue Fox, who possibly has in mind some such body as the "Committee of the National Campaign against Rheumatic Diseases," but I hold to the opinion that for a *particular* practical purpose, such as the formation within the British Medical Association of craft groups, a definition which is not exclusive (in the right spirit) is useless. With the concluding paragraph of Dr. Fortescue Fox's letter I am also in entire agreement; but this is hardly relevant to the subject under discussion—namely, the definition of spa treatment.—I am, etc.,

Harrogate, July 8th. GEOFFREY HOLMES.

THE RELATION BETWEEN MUNICIPAL AND VOLUNTARY HOSPITALS.

SIR,—Mr. C. A. Morton (July 6th, p. 33) has performed a public service by his clear and detailed exposition of the policy of degrading the Poor Law or municipal hospitals. Thus bluntly expressed, the defects of the policy are fairly obvious, and it is not likely to gain universal support. If it really represents the views of those who have been clamouring for the setting up of medical councils with the majority of representatives of the voluntary hospitals, the danger of any such scheme should be made clear.

It is difficult to understand why efforts to reach or maintain a reasonable standard of work in Poor Law hospitals should arouse such indignation in the profession. The attack on the service was formerly grounded, with considerable justification, on general inefficiency; but now the increasing efficiency seems to be regarded as a danger by those who speak for the voluntary system.

I believe Walton is the "largest Poor Law hospital" in England, and the differences between it and the voluntary hospitals are not as stated by Mr. Morton. The consultants have wards allocated to them, and, subject to the general responsibility of the medical officer, carry as much responsibility for their patients as in voluntary hospitals. They are not called in merely to give opinions on selected cases. They are assisted by residents who have all had experience as residents in voluntary hospitals. Practically every case admitted is examined by one of the consultants or by the medical officer.

Some years ago I had considerable experience in running this hospital somewhat on the lines suggested in Mr. Morton's letter, and I have no wish to return to any such system. I am satisfied that a healthy and efficient medical and nursing staff cannot be held together in a hospital which cares exclusively for dull and uninteresting cases. The stimulating effect of a portion of acute cases is essential. Although chronic cases are frequently just as important as acute, they do not make the same appeal to nurses and junior members of the medical staff. In my view the ideal hospital should be large enough to treat cases of almost all kinds of disease, and should have an appropriate specialist staff. Classification should be in the institution and not by separate institutions. Classification in this way in large Poor Law areas has often been carried out to an extent that has been detrimental to the interests of the patients. After all, hospitals deal with human begins, and classification by disease does not exactly correspond with individuals. The plight of a patient in a special hospital when he happens to have some disease in addition to that with which the hospital is especially concerned is not always happy.

The problem the medical profession is concerned with is not the salvation of the voluntary hospitals, but the health of the community as a whole, and this will not be solved by placing the municipal hospitals in an inferior position with an admittedly lower standard of care, but by reasonable co-operation among all the agencies concerned with the public health.—I am, etc.,

HENRY H. MACWILLIAM,
Liverpool, July 8th. Medical Officer, Walton Infirmary.

SIR,—There will be general agreement with the opinion expressed by Mr. Charles Morton in his letter, published in your issue of July 6th (p. 33), that in order to bring the transferred Poor Law hospitals up to the standard of the voluntary hospitals, the city, borough, or county councils would need to appoint visiting specialists to the staffs of their newly acquired hospitals. I trust, however, that few will share his pessimism in assuming such a course to be impossible of achievement, except at the price of general financial ruin due to the cost of whole-time specialists, or, alternatively, if part-time specialists are appointed, of a lethal struggle for existence amongst them.

May I remind Mr. Morton and your readers that, in Bradford, the transference of a large Poor Law hospital to the municipal authority occurred nearly ten years ago: that part-time specialists were appointed for surgery, orthopaedics, gynaecology, midwifery, medicine, radiology, eyes, ears and throats, and anaesthetics; that the scheme has worked excellently, and the hospital runs smoothly as a general hospital, to the great benefit of the sick and of the general practitioners in the city; and that the specialists flourish?

Mr. Morton says: "It is a mistake to suppose that because the Poor Law hospitals are to be transferred to city and county councils the scope of their work should necessarily be altered." In my opinion it is a still greater mistake to assume that alteration of scope will be optional. Bradford is a fair type of the non-university provincial city, and judging by what has happened here the change over to municipal control will necessarily, and very materially, affect the scope of the erstwhile Poor Law hospital. For example, since 1920, when St. Luke's Hospital, Bradford, was taken over by the Health Committee, the number of admissions has steadily increased from 3,804 to 7,176; the average daily number of in-patients from 500 to 710; live births from 158 to 654, and major operations from 428 to 2,219. In spite of this increased work the local voluntary hospital still has a waiting list, though a small one. Obviously such increase in the number of those requiring and seeking hospital treatment was not created by municipalization. The need for treatment existed previously, but did not begin to be satisfied until the Poor Law stigma was removed. And so, I feel sure, it will be in other centres of municipal life.

Mr. Morton's idea of using the transferred hospitals as dumps, to be picked over by the voluntary hospitals for surgical treasure, and where they may deposit their dejecta, is too fantastic to find much favour with progressive municipal bodies.—I am, etc.,

B. HOLROYD SLATER.

St. Luke's Hospital, Bradford, July 12th.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week discussed a money resolution for continuing at the present level the subsidy on houses built for letting. Government speakers promised a bolder Housing Bill after Parliament reassembles in the autumn. Debate also arose on financial proposals for stimulating industry and in settlement of the claims of former Irish civil servants. A Local Government (Scotland) Act Amendment Bill was down for Thursday, but there was doubt about the Government's intention to carry this bill, whose object was to suspend the provisions of the Local Government (Scotland) Act, 1929, so far as these relate to education authorities.

The Government was questioned during the week regarding lunacy law reform. No definite promise was given, but this subject is understood to be prominent in the list of bills which the Ministry of Health will propose to the Cabinet for legislation next winter. Its adoption will probably depend on the time allocated for debates on housing and slum clearance.

The publication and authorization of the Radium Charter was expected to be made during the week, and the hope was that action could be taken upon it before the summer recess.

The Parliamentary Medical Committee met at the House of Commons on July 16th, Dr. Salter in the chair, and noted, as subjects for discussion at future meetings, vaccination, vivisection, sterilization of the mentally defective, the Social Hygiene Council, the Lunacy Acts, radium, the Factories Bill, milk legislation, education in food values, the relation of the State to blind and deaf persons, and maternity benefit. The meeting decided to recommend that members of the Committee who proposed to introduce private members' bills on health subjects should first lay these before the Committee. The report of the Medical Research Council on the value of light treatment was considered by the Committee, which decided to take no action on it at present.

The Committee decided to meet fortnightly, and it discussed at length whether it should consist only of medical members. A decision was taken that only members of Parliament with a medical qualification should be invited to attend the first meeting of the Committee after the summer recess, and these will then decide whether, as in past years, other members representing university constituencies, or other members with special interests, shall be invited to join the Committee. It is hoped that at its second meeting after the recess the Committee will discuss vaccination against small-pox.

Housing: Proposed Rescission of the 1928 Order.

In the House of Commons, on July 15th, Mr. GREENWOOD (Minister of Health) moved a resolution rescinding the Housing Act (Revisions of Contributions) Order, 1928, relating to houses for which contributions were provided under the Housing Act of 1924. He explained that he proposed, until September next year, when the next revision was due, to maintain the subsidy under the 1924 Act at its present level. He proposed that the subsidy under the Chamberlain Act should be allowed to fall, as the late Government desired that it should fall. The resolution, and the bill which would follow, were designed to continue the building of houses to let while a larger and more comprehensive scheme was being prepared and passed through Parliament. He hoped to secure within a relatively short time the adoption of a more determined housing and slum clearance policy.

Dr. FREMANTLE said that the Government's present proposals could not be defended by argument from either side of the House. There was a limit to the amount of money that could be spent on housing, and Parliament had also to consider whether they were spending that money rightly. Members should think for a moment of the gigantic amount which was being spent on subsidies and housing. He would not object if they were getting

their money's worth, but he was bound to say, as a medical officer of health, that many other health schemes were turned down because they would cost, perhaps, £1,000,000, whereas the Government now proposed to increase the housing subsidy to the extent of £6,000,000 a year. Medical officers of health urged that the Treasury should reduce the sums which were spent by the late Government upon housing in order to provide more money for other important health services which called out for aid. All medical officers recognized the gravity of the housing question. They recognized that by improving the housing of the working classes they could do more than in any other way, with the exception of education, to prevent the ill health of future generations. It was important to get proper housing; but they must consider the cost. If the House gave this £6,000,000 to the local authorities under the Local Government Act to use in reduction of rent or in other ways for relieving householders who really needed aid, they would get ten times the value they were going to get from the housing subsidy.

Dr. MORGAN said that the bulk of Dr. Fremantle's speech meant that the housing policy which was being proposed that day—a policy which was put into operation for a considerable time by the Government which he supported—was an extravagant one. Dr. Fremantle said that the expenditure on housing now proposed was wrong. The late Minister of Health had asked the question, "Is the subsidy always to go on?" The Labour party's answer was, "Yes, as long as overcrowding goes on." The report of the special committee appointed by the National Housing and Town-planning Council stated that the Glasgow slums had been described in the annual report of the Scottish Board of Health for 1926. The commissioner appointed to hold the local inquiry wrote, among other things, that it was impossible to draw any picture which could adequately describe the conditions under which they found human beings living in practically the whole of the houses which they inspected. There were, it was true, differences in degree, but all were hopelessly unfit for habitation. Damp was present everywhere, the walls and ceilings in a large number of houses being literally soaking. Everywhere they noticed an almost total lack of sanitation. Conveniences being few, and for the most part out of repair, and in some cases leaking down the stairs, and even into the houses. A very revolting feature of the slums was that the majority of the houses were infested with bugs. The Labour party knew of these conditions, and that was why they wanted money spent on housing. In his final remarks Dr. Fremantle made a very excellent suggestion, which, however, was not his own, although he said it was his alternative policy. It was well known, and had been published in many books on slum clearance. He suggested rent subsidies, or family allowances, but that was the only contribution that he made to the discussion. Here was a professional man, who had been a medical officer of health, and who ought to know about housing conditions, coming there and making a speech such as he had made, at a time when people were crying out for houses, when they were living in conditions of overcrowding, when family life was practically in abeyance, when the Housing Acts were inoperative, and when children's whole morale was being disturbed by the conditions under which they existed. The policy of the Government was not extravagant. They wanted the Minister of Health to increase the subsidy still further, and to see more houses built.

The resolution was agreed to.

Dangerous Drugs.

Thefts of Drugs from Doctors' Cars.—On July 11th Mr. GEORGE OLIVER asked the Home Secretary a question concerning thefts of drugs from motor cars belonging to doctors. He desired to know whether, in view of the increase of this class of theft and the consequent danger, the Home Secretary proposed to take steps to prevent medical practitioners leaving dangerous drugs unattended. Mr. CLYNES replied that there had been a number of such thefts, but the police were satisfied they were ordinary cases of petty larceny and had no connexion with any form of traffic in dangerous drugs. Mr. Clynes said he had difficulty in seeing what action he could usefully take. It was desirable that medical practitioners and others who had dangerous drugs in their possession should be particularly careful to avoid risk of their being lost or stolen. He hoped the publicity given to the matter would lead to greater care being taken. Mr. OLIVER asked if Mr. Clynes was aware that twenty-nine cases of this description had occurred during the last twelve months, and that on July 10th, at Bolton, when such drugs were stolen, the press had stated that sufficient to kill twenty people had reached the hands of children. Mr. CLYNES said that he was not aware of any such occurrence. Mr. OLIVER asked whether Mr. Clynes would suggest to the medical profession that if cases of this kind increased and continued at the present rate some method would be adopted for enforcing penalties. He further asked whether Mr. Clynes knew that criminal negligence on the part of miners or railwaymen was punished with imprisonment. Mr. CLYNES said that if the answer he had given had no effect further steps might be taken.

Manufacture of Morphine at Ghazipur.—Mr. BENN (Secretary of State for India), in an answer to Major Pole, on July 11th, gave figures showing the amount of morphine manufactured at Ghazipur in the last five years. The amount manufactured from October, 1927, to September, 1928, was 165 lb., of which 119lb. was issued in India. The balance in hand on September 30th last was 144 lb. No morphine had been exported from Ghazipur to the United Kingdom since 1923-24, in which year 430 lb. was so exported. There were elaborate and strict regulations under the Indian Opium Act No. 1 to regulate the sale of the drug by licensed dealers for genuine medical and scientific requirements. These regulations provided that sales must be vouched by qualified medical practitioners.

National Health Insurance.

Mr. T. LEWIS asked, on July 11th, whether Mr. Greenwood would bring in a bill to restore the State grant on national health insurance benefits and administration expenditure to the two-ninths, as provided in the National Health Insurance Act, 1924. Mr. GREENWOOD replied that he would make no statement pending the results of the general survey which the Government was making of the national health insurance and pensions schemes.

In the reply on the same date to Mr. Daggar, Mr. Greenwood said he knew that a few of the smaller approved societies and branches, covering less than 1 per cent. of the total number of insured persons entitled to dental benefit, could not for the time being consider claims from their members for that benefit, by reason of the depletion of the annual sums available for the purpose. Mr. DAGGAR asked whether Mr. Greenwood proposed to introduce legislation which would make it binding on such societies to honour the obligation made with their members. Mr. GREENWOOD replied that there was no such obligation. Dental benefit was merely an additional benefit which might be provided by a society within the limits of the amount available in each year for benefit.

On July 16th Mr. GREENWOOD, replying to a question, said no regulations had yet been made under the National Health Insurance Act governing the provision of ophthalmic and other forms of treatment of insured persons in clinics, and, consequently, no clinics had been set up under the Act. Dental and ophthalmic clinics had been set up by private enterprise, and some insured persons had elected to obtain through them treatment, towards the cost of which their approved societies had contributed by way of additional benefit. No official recognition had yet been given to any of such clinics. Their continued use as agencies providing treatment to insured persons entitled to additional benefits would be conditional on their complying with requirements which might in due course be laid down by regulations under the Act.

Radium.

In a reply to Sir Charles Cayzer, on July 11th, Mr. GREENWOOD said he could not adopt the suggestion that local hospital authorities sending contributions to the National Radium Fund should be allowed to earmark them so that they should be doubled by the State grant. Mr. Greenwood said the contributions from public funds towards the purchase of radium were subject to a maximum limit of £100,000, and an equal sum had already been raised by private subscription. The claim of provincial hospitals to receive some assistance from the central fund was now being dealt with, and a public statement would shortly be made on the manner in which the radium was to be allocated.

Small-pox.—During the twelve months ended May 31st there were 39 deaths in England and Wales in which small-pox appeared in the coroner's or medical certificate as the cause or one of the causes of death. In the same twelve months 29 deaths were returned as associated with vaccination.

Tuberculosis in the Navy.—Mr. AMMON, in an answer to Sir Bertram Falle, on July 11th, said that in the calendar year 1928 there were 1,081 seamen and marines invalided from the Royal Navy, and 132 cases were found to be attributable to service. The number invalided with tuberculosis was 140, of which 42 were found to be attributable to service.

Effect of the Local Government Act on Maternity and Child Welfare.—Mr. SIMON asked Mr. Greenwood, on July 11th, whether he was aware that persons interested in maternity and child welfare work feared the provisions of the Local Government Act, 1929, would hamper the development of this work. He further asked if the Minister of Health proposed to restore the percentage grant for these services. Mr. GREENWOOD said he was aware of this apprehension in certain quarters, but could not at present undertake to introduce legislation for the continuance of percentage grants for maternity and child welfare work. The effect of the development of the public health services of the new system of grants would be carefully watched. He had no reason to suppose that any restriction on the development of maternity and child welfare services was contemplated by local authorities; he saw no ground for issuing a special circular on the subject.

Milk and Maternity Centres.—Sir GEORGE PENNY, on July 11th, asked whether the Minister of Health proposed to make a greater allowance for milk and maternity centres than was granted by the late Government. Mr. GREENWOOD replied that the maximum expenditure during the current year by each local authority for milk to mothers and babies which would be recognized by the Ministry of Health for grant had been fixed last March. He would consider on its merits any case in which he was asked to approve additional expenditure for this purpose.

Experiments on Animals.—Mr. SHORT, replying to Mr. Bromley on July 15th, said that applicants for licences or certificates under the Cruelty to Animals Act, 1876, for the performance of experiments on animals were not required to state

the number of animals they proposed to use for experiments. The Home Office had no record of the number of animals used as distinct from the number of experiments performed under the Act in 1927, nor of the number of dogs and cats used for experiments in 1927 under Certificate B, *plus* E E. Section 5 of the Act, which governed Certificate E E, did not distinguish between cats and dogs. On July 15th Mr. MACDONALD told Sir R. Gower that he could not undertake to give special facilities for a bill to make the vivisection of dogs illegal. Private members interested would no doubt use, as before, the facilities they had for testing the opinion of the House on the subject.

Chemical Warfare: Experiments with Animals.—Mr. SHINWELL (Financial Secretary, War Office), answering Mr. Oliver on July 10th, said he was advised that the experiments with living animals at the Chemical Warfare Experimental Station were essential to obtain data for adequate defence against poison gas and for evolving efficient methods of treating human beings who might become gas casualties.

Schools for Mentally Deficient Children.—Sir C. TREVELYAN, replying on July 15th to Dr. Morgan, said that the number of mentally deficient children attending certified special schools in England and Wales last year was 15,339. A joint committee of the Board of Education and the Board of Control had recently presented a report on the future of such institutions, which was receiving his careful consideration.

Lunacy Law.—On July 15th Miss LAWRENCE told Mr. Hore-Belisha that the question of putting into operation the recommendations of the Royal Commission on Lunacy Law was under consideration, but the Minister of Health was not at present in a position to indicate when it would be practicable to introduce legislation on the subject.

Highlands and Islands (Medical Services) Fund.—Mr. ADAMSON, replying on July 16th to Sir Robert Hamilton, said that the war-time accumulations in the Highlands and Islands (Medical Services) Fund would be exhausted within the next few months, and the present statutory income of the Fund would require to be supplemented. There had been no curtailment of established services assisted from the Fund, and certain expansions had been sanctioned from year to year, but other desirable developments had been delayed pending reconstitution of the Fund. He hoped to be able to submit proposals to the House on an early date.

Notes in Brief.

The Government is considering the lowering of the pension age for the blind from 50 years to 40 years.

Mr. Greenwood promises to consider representations he has received for the provision of pensions for the deaf and dumb similar to pensions already instituted for the blind.

In the year ended March 31st, 1929, in England and Wales £23,200,000 was contributed by, or in respect of, insured persons under the National Health Insurance Act, and £20,900,000 under the Widows Contributory Pensions Act.

Medico-Legal.

POISONING BY ASPIRIN.

AT the Sussex Assizes on July 9th a woman, aged 25, charged with poisoning her infant by means of aspirin, was found guilty but insane, and the judge directed that she be kept in custody as a criminal lunatic until His Majesty's pleasure be known. It appeared in evidence that the accused had dissolved 300 tablets of aspirin, each of 5 grains, in a pint of water, and, having given two dessertspoonfuls to the infant, had taken the rest herself; the infant died the following day. Dr. E. J. Budd-Budd stated that for a child two dessertspoonfuls of a solution containing 1,500 grains of aspirin to the pint would be a fatal dose. The defence was that the accused was insane at the time she committed the act.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE Radcliffe Scholarship in Pharmacology has been awarded to J. R. Braybrooks (New College) and G. S. Grist (Pembroke College), who were equal in merit. The Theodore Williams Scholarship in Pathology, of the annual value of £60 and tenable for two years, is awarded to J. R. Braybrooks.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

THE following awards have been made at University College in the Faculty of Medical Sciences:

Ent[illegible]

An[illegible]

[illegible] Morton; Junior Class (histology and embryology—prize equivalent to silver medal), G. Qvist.

Physiology and Biochemistry: Schafer Prize, L. E. Bayliss; Senior Class (prize equivalent to gold medal), E. A. Devenish; Junior Class (prize equivalent to silver medal), D. A. Andersen; (additional silver medal), Margaret H. Morton.

Organic and Applied Chemistry: General course (prize equivalent to silver medal), Esther Copperman.

Pharmacology: Silver medal, Kitty K. Cohen.

UNIVERSITY OF SHEFFIELD.

THE following candidates have been approved at the examinations indicated:

M.D.—Janet Breakey.

FINAL M.B., CH.B.—T. Ellis,* T. H. Fullar, W. H. Carlisle, Iris M. Moody, I. Slesnick.

* With honours.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council meeting of the Royal College of Surgeons of England was held on July 14th, when the President, Lord Moynihan, was in the chair.

Council Election.

The President stated that, as a result of the poll for the election of four Fellows into the Council, Sir H. J. Waring, Mr. C. H. Fagge, and Mr. W. Sampson Handley were re-elected and Mr. Graham Simpson of Sheffield was elected a member of the Council.

The President stated that Mr. Simpson becomes substitute member of Council for Sir James Berry until 1931.

Sir H. J. Waring, Mr. Fagge, Mr. Handley, and Mr. Simpson were introduced and took their seats in the Council.

Professors and Lecturers.

The following were elected professors and lecturers for the ensuing year:

Hunterian Professors.—Sir John Rose Bradford, K.C.M.G. (one lecture); Victor Ponney (one lecture on the surgical treatment of carcinoma of the cervix); John Herbert Fisher (one lecture on some points in connexion with perforating injuries of the eyeball); George Ernest Gask, C.M.G. (one lecture on a contribution to the treatment of epithelioma of the tongue by radium); William Sampson Handley (one lecture on the papilloma and its metastasis); Sir Arthur Keith (six further lectures on human anatomy—structures old and new); Geoffrey Langdon Keynes (one lecture on the treatment of carcinoma of the breast).

Arris and Gale Lecturers.—William Mc Adam Eccles (one lecture on anatomy, orthodox and heterodox, in relation to surgery); Ethelbert Best Flint (one lecture on the association between gall-bladder lesions and hepatitis in the human subject); Ronald H. V. Botham Robinson (one lecture on the surgical treatment of cholecystitis).

Erasmus Wilson Lecturers.—Clement Edward Shattock (three demonstrations on pathology); Cecil Pembrey Grey Wakeley (three demonstrations on pathology).

Arnott Demonstrator.—Sir Arthur Keith (six demonstrations on the contents of the museum).

The President reported that, as Dr. M. E. Delafield had been unable to undertake the duty of examining at Part I of the examination for the D.P.H., he had nominated Dr. John Eyre in his stead.

Diplomas.

The diploma of Fellowship was granted to R. L. Almond.

The diplomas of Membership were granted to V. L. Misso and R. M. Sargent, who had passed the necessary examinations and complied with the regulations.

The following diplomas were conferred jointly with the Royal College of Physicians of London:

LARYNGOLOGY AND OTOLOGY.—B. R. Chaudhri, P. Hicker, G. J. Hutchison, R. Kacker, W. A. Kerr, K. S. May, R. F. Paterson, C. L. Rosenfield, G. Vaishnavi.

1 [illegible] Barber, Flora H. MacD. Calder, Viola C. S. W. Davies, J. H. Ewen, E. A. Haslam-Rao, Kathleen M. Told.

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship stating that at the examination concluded on June 13th 163 candidates were examined, of whom 47 were approved and 116 rejected.

A report from the same Board was also read announcing the award of the Hallett Prize for the examination concluded on June 13th to Leith Alexander Riddell, M.B., Ch.B., New Zealand.

Licences in Dental Surgery were granted to 40 candidates.

Election of Officers.

The following were elected for the ensuing year: President, Lord Moynihan; Vice-Presidents, Mr. C. H. Fagge and Mr. Warren Low; Physiological Curator, Mr. R. H. Burne; Pathological Curator, Mr. C. F. Beadles; Honorary Curator of the Odontological Collection, Sir Frank Colyer.

Appointments.

Mr. C. J. S. Thompson was reappointed Honorary Curator of the Historical Section of the Museum (including surgical instruments and appliances) for the ensuing year.

Mr. Harold Jackson Burrows, F.R.C.S., was appointed Beaverbrook Research Scholar of the Royal College of Surgeons for two years from January 1st, 1930. In the meantime he will work at the Research Hospital, Cambridge, on tissue culture research.

Mr. W. R. Le Fanu, B.A., second librarian of the Hellenic Society, was appointed assistant librarian for one year from October 1st, 1929. A portrait group of the Council in 1927–28, painted by Mr. Moussa Ayoub, was presented to the College by Lord Moynihan and was accepted with thanks.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved at the examination indicated:

MASTER OF MIDWIFERY.—B. P. Baliga, M.B., B.S., C. A. Birch, M.D., W. C. V. Brothwood, M.B., Ch.B.

TESTIMONIAL TO SIR RONALD ROSS.

THIRD LIST OF CONTRIBUTORS.

ON May 11th (p. 879) we published a letter from Sir James Barr and others announcing that a fund, called the Ross Award Fund, was being started in order to give some recognition to Sir Ronald Ross for his discoveries on the mode by which malaria is carried, and for his lifelong efforts regarding the prevention of that disease. The letter stated that donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15, cheques to be crossed "Ross Award Fund a/c." The names of those who had contributed to the Fund up to May 17th were printed in our issue of June 8th (p. 1065), and a second list of donors appeared in our issue of July 13th (p. 76). We now print a third list of those whose donations, amounting to £458 8s. 6d., were received during the month of June. The total amount contributed up to June 30th was £3,663 17s. 4d. The list published below does not include anonymous contributors or contributors whose initials only have been supplied.

M. H. Alson, J. Alston, Mrs. E. G. Ayton, Mrs. L. Adams, W. J. Ashworth, Charles Allen.

C. Burt Brill, Mrs. Beesley, R. E. Burlston, H. S. Badcock, Mrs. Banan, H. Vaughan Barber, Miss M. H. Benson, Commander of s.s. *Balmanald*, Florence B. Bright, H. Brock, Miss M. E. Butcher, A. W. Blomeley, Mrs. Charles Bishop, Mrs. Jessie Ballantyne.

Dr. Alfred Cox, Robert Corry, Alan A. Campbell.

Mrs. Delaney and Mrs Webb, B. E. Dalton, G. F. Donne.

Mrs Mary Haldane Eckford, Mr. J. D. Edelston.

M. L. and E. Goss, Mrs Henry Gordon-Watson, Messrs. *Guthrie and* Co., Ltd.

Dr. H. Mather Hare, Dr. W. Savile Henderson, Dr. Hubert Henstock, Dr. A. E. Horn, Mrs. Heron, Councillor Miss Hartley, Mrs. Hay, T. Holmes, W. Hargreaves, Albert Hovenden, W. L. Harrison.

Margaret Isaacson.

Colonel F. S. Jackson, Mrs. Johnston, C. Jennings.

Dr G. C. Low, Lincoln Medical Society, P. Leftwich.

Mr. and Mrs. W. Mason, Mary Stewart Miller, M. L. Martin, Charles Maggs, Malaya General Co., Ltd., Sedenak Rubber Estates, Ltd, Mengkibol (Central Johore) Rubber Co., Ltd., and Pontian (Malay) Rubber Co., Ltd., Mr. and Mrs J. N. Metaxa, Mrs. Edith E. MacIver.

Miss H. G Nutter, E. Nichol, Hon. J. B. Napier.

Mrs. Paulsom, S. C. Payne, E. Pearce, F. W. Pelke.

Miss D. Ruddick, R. F. Ruddick, Mr. W. G. Rawlingson, Dr. S. M. Ross, Mrs. E. G. Reid, Mr. F. Renfield.

Miss C. L. Skeat, L. A. Stephens, Mrs. Sherriff, Dr. P. S. Selwyn-Clarke, D. M. Stevenson, Miss B. Scott, A. W. Still, F. Simpson, J. H. Sargant.

G. A. Taylor.

The Misses Vernham, Frank A. Venrenen.

Dr. F. Parkes Weber, Dr. Watson-Williams, A. B. Warde, C. J. M. Whitaker, E. and M. Williams.

Dr. Reginald A. Yeld.

Medical News.

MR. C. THURSTAN HOLLAND, Ch.M., F.R.C.S., has been elected president of the British Institute of Radiology (with which is incorporated the Röntgen Society) for the session 1929-30, which commences in October. The honorary treasurer is Dr. D. B. McGrigor, and the honorary secretaries are Dr. Stanley Melville and Mr. George Shearer, D.Sc.

THE new Orthopaedic Hospital at Harlow Wood, near Mansfield, Notts, will be opened by H.R.H. the Duchess of York on Saturday, August 3rd. This voluntary hospital is being built in connection with the work of the Nottingham District Cripples' Guild, as a central hospital school for patients attending the clinics in Nottingham, Hucknall, Loughborough, Mansfield, Newark, and Worksop. An ideal site of fourteen acres was presented by the Duke of Portland, and a fully equipped country hospital is being erected where children may be treated and educated amid perfect surroundings. There is, in addition, accommodation for adults.

WE are informed that Dr. George P. Pitkin, of Hackensack, New Jersey, or Dr. Frank A. Kelly, of Detroit, Mich., will give demonstrations of controllable spinal anaesthesia with spinocain, at Bristol to-day (July 19th); at the Rotunda Hospital, Dublin, on the 20th and 22nd: at St. Bartholomew's Hospital, London, on the 22nd, at 1.30 p.m., and on the 23rd at 9 a.m. and 1.30 p.m.; at St. Peter's Hospital, London, on the 22nd at 2.30 p.m.; at Liverpool on the 23rd; and at Manchester on the 27th.

At the third International Congress of the World League for Sexual Reform, to be held at the Wigmore Hall from September 8th to 14th, under the presidency of Drs. Havelock Ellis, August Forel, and Magnus Hirschfeld, sessions will be devoted to discussions on the following subjects: marriage and divorce; birth control, abortion, and sterilization; prevention of venereal disease and prostitution; and sex and censorship. Among those who have promised to read papers are Professor Patrick Geddes, Captain G. L. F. Pitt Rivers, the Hon. Bertrand Russell, Mr. Bernard Shaw, Dr. B. P. Wiesner, and Dr. C. V. Drysdale.

THE Fellowship of Medicine announces that the course in gastro-enterology which it was proposed to hold from July 22nd to 26th has been postponed until September 30th to October 4th, when it will be conducted at the Prince of Wales's Hospital, Tottenham. There will be three courses in August: one in urology at All Saints' Hospital, Vauxhall Bridge Road, will be held each afternoon from July 29th to August 24th; one in diseases of children at the Queen's Hospital for Children, Bethnal Green, will occupy most of each day from August 12th to 21st; and the third, a whole-day course in medicine, surgery, and the specialties at the Queen Mary's Hospital, Stratford, will continue from August 26th to September 7th. Courses in September will comprise: diseases of the chest, at Brompton Hospital from September 9th to 14th; diseases of infants, at the Infants Hospital from September 9th to 21st; psychological medicine, at the Bethlem Hospital on Tuesdays and Saturday mornings from September 10th to October 5th; and medicine, surgery, and the specialties, at Westminster Hospital from September 16th to 28th. The following special courses have been arranged in addition to those in the list published for the year: M.R.C.P. evening course, October 15th to December 6th, Tuesdays and Fridays, at 8.30 p.m., at the Medical Society Lectures Room; and a whole-day course in medicine, surgery, and the specialties at the Metropolitan Hospital, Kingsland Road, from October 21st to November 2nd. Syllabuses of all special courses, together with information in regard to the general course of work, may be obtained on application to the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE fourth ordinary general meeting of the Ross Institute and Hospital for Tropical Diseases was held at the Institute, Putney Heath, on July 3rd, when the chairman of the council, Sir Charles McLeod, presented the annual report and accounts for 1928. After commenting on various details in the report, he pleaded for a greater measure of financial support in view of the absence of any endowment of the Institute, and also warmly commended the appeal which was being made on behalf of a testimonial to Sir Ronald Ross. Two representatives of the Ross Institute and Hospital, Sir Malcolm Watson and Major Lockwood Stevens, spent five months in touring India and Ceylon to prepare the ground for the formation of local committees to work in conjunction with the Institute's central committee, which aims at "giving direct assistance in tropical industries." These visitors got into touch with the health officials of many parts of the Indian Empire, as well as with many branches of the voluntary co-operative antimalaria movement, which has made encouraging progress in Bengal. Mining areas, tea gardens, great cities, and small villages were visited, and the report shows how important a problem malaria is in them all. It seems probable that the major needs for malaria control in India are already well known to those working on the spot. It may be that discussion with visiting experts will help to overcome the difficulties in the way of putting the necessary measures into force.

THE ambulance hut at the annual show of the Royal Agricultural Society of England, held at Harrogate from July 9th to 13th, comprised a dressing room, two small wards, and a kitchen; it was in the charge of the Harrogate nursing division of the St. John Ambulance Brigade, by whom it had been equipped. Assistance was also given by the Ripon nursing division and by the men of the Barnoldswick and Ripon ambulance divisions, there being no men's division in Harrogate. During the whole period of the show ambulance men and St. John nurses were on duty, and dealt with upwards of 200 casualties—fortunately, none of a serious nature—which included bites by animals, cuts from machinery, sprains, bruises, scalds, septic wounds, fainting attacks, and collapses. Colonel Scatterty, M.D., and Dr. Wesley Smith (divisional surgeon) were in attendance every day, and many calls were made at the hut by other doctors visiting the show.

THE Minister of Health received a deputation, on July 16th, from the National Anti-Vaccination League. Mr. H. G. Chancellor and Mr. Arnold Lupton urged that, in view especially of the inadequacy of the conscience clause, the Vaccination Acts should be completely repealed. They submitted to the Minister their grounds for believing in the inefficacy of vaccination as a protection against small-pox and in its extreme danger to health. In support of their views they quoted numerous cases of deaths following vaccination. Dr. Beddow Bayly referred to the cases that have occurred of post-vaccinal encephalitis, and pressed the point that as the small-pox now prevalent was of so mild a character it was unnecessary to urge vaccination. The Minister said, in reply, that he thought that politically it would be very difficult to pass through Parliament a bill to repeal the vaccination laws, but he could not, of course, make any statement on the policy involved without consulting the Cabinet. He promised, however, that he would

give his close personal attention to the statements that had been presented to him by the deputation.

SIR ROBERT PHILIP'S paper entitled "The principles underlying a scheme of anti-tuberculosis measures in any country" has been reprinted from the *Transactions* of the fourteenth annual conference of the National Association for the Prevention of Tuberculosis, by direction of the council.

LISTS of medical practitioners serving as members of local authorities or their subsidiary bodies in Great Britain have been published in recent issues of the *Journal*. We have since received notification that Dr. E. H. M. Stancomb is a co-opted member of the Education Committee of the Southampton Borough, and that Dr. A. J. Knowlton, J.P., and Dr. E. Sakoschansky are members of the Southampton Borough Council.

THE eighth Rumanian congress of oto-rhino-laryngology will be held at Bucarest from October 26th to 28th, under the presidency of Dr. Christian Oroseo. Further information can be obtained from the general secretary, Dr. Lazare Magersohn, 81, Calea Mosilov, Bucarest.

Letters, Notes, and Answers.

QUERIES AND ANSWERS.

INTESTINAL STASIS WITH SPASM.

"B. M." (Boscombe) writes: I should be grateful for advice in the treatment of the following case of intestinal stasis with colonic spasm. The patient, a man aged 42, was operated on eight years ago for duodenal ulcer. He has extremely obstinate constipation which aperients fail adequately to remedy. The motions are solid, semi-solid, or fluid, according to the aperient taken. His weight is 8 st. 4 lb., though eighteen months after the operation it was 10 st. 7 lb. He is irritable and has insomnia, with sudden fits of drowsiness during the day. He is always tired and seems to have severe toxaemia. His diet is as follows: Breakfast: lightly boiled egg, porridge, toasted wholemeal bread, a small cup of tea. Lunch: small quantities of ham, potatoes, green vegetables, cheese, wholemeal bread, and a pudding. Tea: wholemeal bread and tea. Dinner: very little fish, vegetables, pudding or fruit, cheese, bread, and a biscuit. I should like to know if new potatoes may be included in the diet, and what kinds of fruit are allowable.

THE PLURAL OF LINCTUS.

"PERDIX" (London, S.E.) writes: I should be obliged if some of the classical scholars among your readers would inform me of the plural of *linctus*. I am told by people who speak with an air of authority that it is *lineti*. I was under the impression that it was derived from *lingo*, I lick, and that it was a masculine noun with genitive *linctūs*, and declined like *portus*, in which case the nominative plural is *linctūs*.

*** The Oxford English Dictionary gives *linctuses* as the plural of *linctus*.

PAINFUL HEEL.

"AJAX" writes: I am much interested in the discussion of painful heel, as I have suffered from this condition for seven years, and can get but little relief. *X*-ray examinations show no obvious outgrowth of bone or other malformation. It is aggravated most by playing tennis, especially on a hard court. It is also especially painful on getting up in the mornings, or on restarting to walk after a rest. Towards the centre and back of the heel underneath can be felt something which gives the feeling of a movable nodule of some kind, and it would appear that the pain came from it, as it is most painful on deep pressure. Can anyone help me?

"N. D." (Guernsey) writes: I passed through Bart's 1895-98. One of my teachers laid it down categorically that this affection meant gout or syphilis, and nothing else. So I have found it. The last case I treated, a young married man with two healthy children, gave a positive Wassermann reaction, and a short course of N.A.B. injections cured a very troublesome and intractable complaint.

UMBILICAL DISCHARGE.

DR. CASSIE E. PRATT (Bexley Heath) writes: With reference to the above condition I should like to report a case which came under my care recently. A woman, aged 24, gave a history of umbilical discharge with soreness, occurring at intervals over a number of years, but much worse during the past month. There was much excoriation, with a milky, offensive discharge. The umbilicus was funnel-shaped, and similar to the one described by "B. B. L." on July 6th (p. 56). On passing a probe I removed a hard white concretion the size of a melon seed—undoubtedly the cause of her trouble. It was certainly a collection of sebaceous matter—epithelium, soap, and debris. I gave instructions for careful cleansing, and the condition should now clear up.

LETTERS, NOTES, ETC.

RADIUM FOR LONDON HOSPITALS.

LORD DONOUGHMORE, Treasurer of the Thank-offering Fund organized by King Edward's Hospital Fund for London and the National Radium Fund, writes with reference to an article in a widely circulated newspaper suggesting that money received for radium is lying idle: "I would like to point out that only part of the money received for the Thank-offering Fund was subscribed for the purchase of radium. The national radium to which the Government are contributing £100,000 will be bought and held by the National Radium Trustees. Meanwhile, the producers of radium and the manufacturers of platinum containers are being kept busy in supplying King Edward's Hospital Fund, following on Sir Otto Beit's generous gift of £50,000 to that Central Fund for the purchase of radium to be loaned to hospitals. The facilities for the radium treatment of patients in the London hospitals are thus being increased week by week. While the appeal for the National Radium Fund is already oversubscribed, the other branch of the Thank-offering Appeal at 103, Kingsway (that is, King Edward's Hospital Fund for London), which will provide for the many other needs of the hospitals, some equally pressing, is still open."

GUILD OF SS. LUKE, COSMAS, AND DAMIAN.

COLONEL P. W. O'GORMAN, M.D., informs us that a general meeting of the Medical Guild of St. Luke, St. Cosmas, and St. Damian will be held under the auspices of the Manchester Branch on Wednesday, *July 24th, from 4 to 6 p.m.*, in the Holy Name Hall, 2, Portsmouth Street (corner of Dover Street), Manchester. The Right Rev. T. Henshaw, Bishop of Salford, will hold a reception at 4 o'clock, which will be followed by an address by Dr. J. W. O'Donovan, of the London Hospital, on "Contacts of English medicine with Catholic traditions." Refreshments; robes optional; all doctors welcome. The meeting will conclude with Pontifical Benediction at the Holy Name Church at 6 o'clock. Trams 41, 42, and 45 from Albert Square and Piccadilly pass near the hall.

SPONTANEOUS RUPTURE OF HYDROCELE.

DR. R. COCK (London, E.) writes: Early this year I had under my care a man, aged 31, who had a hydrocele on the left side, about the size of an orange and very tense. I was going to tap it, but the patient found it too painful to handle, so I did not do so. The following day the patient said that it was now painless and had completely disappeared, but that the penis was very swollen. On examination I found much swelling—in fact, bursting seemed imminent, so I advised rest and cold applications; the swelling cleared up very shortly. It would be interesting to know whether other practitioners have come across similar cases.

MEDICAL BOOK-KEEPING.

MR. W. P. SYMES, of Messrs. H. K. Lewis and Co., Ltd., delivered a lecture, on July 12th, at Gordon Hall School of Pharmacy for Women, Drayton House, W.C., on medical book-keeping and the duties of a dispenser book-keeper in general practice. The lecture was illustrated by demonstrations, and was followed by questions and discussion, and the principals of the school decided to add this subject to their syllabus.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 52, 53, 56, 57, and 58 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 35.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

56. Non-diabetic Glycosuria.

W. B. MEYER (*Med. Welt*, May 4th, 1929, p. 637) sums up the diagnostic points in differentiating glycosuria due to a true diabetes from that associated with other conditions. Diabetic glycosuria is characterized as follows: it is directly dependent on the amount of carbohydrate intake; has a definite limit of tolerance; can be diminished or even removed by insulin; is accompanied by hyperglycaemia; and is manifested by a characteristic blood sugar curve. Non-diabetic glycosuria may be caused experimentally by stimulation of the floor of the fourth ventricle and by injection of adrenaline; such glycosuria is transitory and is not accompanied by the symptoms which arise after removal of the pancreas. Pathological conditions in man which may cause a similar transitory glycosuria include any organic cerebral disturbance, such as trauma, tumour, or haemorrhage; the glycosuria is more or less independent of the carbohydrate intake and shows no evidence of disturbed metabolism. To this group belongs the glycosuria caused by drugs and toxins, such as strychnine, morphine, chloroform, and fevers, which damage the central nervous system. Regarding endocrine glycosurias, that of hyperthyroidism is caused by increased suprarenal secretion. In acromegaly the position is peculiar, as there is possibly a connexion between the hormones of the pituitary and the pancreas; no appreciable damage is caused, dietetic treatment is unnecessary, and insulin would not affect the cause. In the preceding conditions the etiology is more or less clear; as regards the next group, however—renal glycosuria—opinions are divided, but it may be defined as a faulty condition of the kidney itself, the general metabolism being unaltered. The signs appear after the injection of phloridzin, and the glycosuria of pregnancy is also comparable. Frank states that every pregnant woman has a latent renal diabetes; even if sugar is excreted only in very small quantities these women are subject to a high degree of acidosis. Actual treatment is not necessary, but an excess of sweets should be avoided; insulin, as in glycosuria innocens, has no effect. This last-named condition is important diagnostically; it occurs at all ages, gives rise to no symptoms, and is often discovered accidentally during an examination for life insurance. Its differential diagnosis from true diabetes is therefore of great importance. There are four points characteristic of it: the amount of glycosuria is almost independent of the carbohydrate intake; there is no limit of tolerance; insulin does not diminish or stop the glycosuria; in most cases the blood sugar is normal and the curve rises and falls sharply. There is an intermediate group of cases usually showing a high blood sugar figure, with its characteristic symptoms resembling true diabetes but uninfluenced by insulin. Such cases are possibly responsible for the so-called failure of insulin therapy. Regarding prognosis, glycosuria innocens is regarded as a developmental failure, and it does not predispose to diabetes. The intermediate group cannot be regarded so favourably with any certainty; it requires treatment by diet and insulin to control the symptoms.

57. Aphasic and Monoplegic Migraine.

L. MORENAS and J. DECHAUME (*Journ. de Méd. de Lyon*, April 20th, 1929, p. 259) discuss the connexion between migraine and epilepsy. Although it is rare, Charcot and other authorities have described a paretic type of migraine with or without aphasia. The authors record the case of a man, aged 66, who had had attacks of migraine complicated by aphasia, paraesthesia, convulsions of a Jacksonian type, and transient brachial monoplegia. The first attack occurred when the patient was 22 years old and was in the army. The whole left arm was involved, formication and cramps being succeeded by epileptiform convulsions and paralysis of the limb; this lasted for a few hours and was accompanied by severe headache, followed by mucous vomiting, which relieved all the symptoms. No further attack occurred for twelve years, but since the age of 34 they have recurred every two or three months. The patient's blood yielded a negative Wassermann reaction, and there was no history of syphilis. Two children suffered from nervous disorders, one son being an epileptic. The patient suffered from bradycardia, abnormal variations in blood pressure, and vasomotor disturbances, all pointing to vago-sympathetic imbalance. The alkalinity of the blood was increased. For some days before his death the patient exhibited signs of mental deficiency, with partial right hemiplegia, paralysis of the sphincters, and transient aphasia. The hemiplegia and aphasia disappeared for a time and he became excited and violent; this was followed by gradually deepening coma and right hemiparesis. Babinski's and Kernig's signs were absent. The patient died in coma; his last illness was of seven days' duration. The necropsy revealed only punctiform haemorrhages resembling those which are found in experimental shock. The authors think that these facts constitute clinical and anatomical proofs of the vasomotor origin of the symptoms of migraine. They claim to have established an etiological link between migraine and epilepsy, and exhibit this case as a transitional type between those two syndromes.

58. Transient Hemiplegia.

E. KAUFMANN (*Deut. med. Woch.*, February 1st, 1929, p. 184) reports a case of transient hemiplegic attacks in a man aged 62, and discusses the etiology of this condition. His patient began with symptoms of vertigo, cardiac irregularity, and occasional sensations of impending death. There was some evidence of involvement with the peripheral circulation, including pallor, and marked variations of the blood pressure from time to time. A diagnosis was made of commencing aortic sclerosis, and treatment with hypertonic medicaments was continued for four months with some little improvement. A sudden acute attack then occurred, the patient became gravely collapsed, with a thread-like pulse, the rate being 60. There was evidence of slight hemiparesis on the right side of the body and face, together with an increasing motor aphasia. The tendon and bone reflexes were briskly increased on the right side, but the signs of Babinski and Oppenheim were absent and there was no ankle clonus; the left side was normal. Remedies for shock, such as coramine, were administered without effect, but the intravenous injection of hexatone—a water-soluble form of camphor—brought about marked improvement. The author discusses the production of such fleeting localized cerebral symptoms, and comes to the conclusion that in his case there was sufficient evidence of arterial degeneration, together with a possibility of involvement of the lenticulostriate artery, which is known to be one of the commonest sites of endarteritis. The involvement of the neighbouring basal ganglia and the failure of the pyramidal reflexes is thereby explained.

Surgery.

59. Carcinoma of the Hand.

M. L. MASON (*Arch. of Surg.*, May, 1929, p. 2107) reports a series of 25 cases of carcinoma, pre-carcinomatous ulcers, and *x*-ray dermatitis, and defines four main groups of carcinoma of the hand: (1) those appearing as the result of trauma or irritation or on the basis of a scar; (2) those arising from a previous growth, such as a wart or naevus; (3) carcinomas developing *de novo* from the previously unchanged skin; and (4) a group in which the data are too meagre for classification. The carcinoma usually appears on the dorsum of the hand, and rarely on the palm or volar surfaces of the fingers; *x*-ray carcinoma is always on the dorsum of the hand and usually on the left. Carcinomas arising on the hand have a long chronic course; in the pre-ulcerative stage a small tumour may appear over a metacarpo-phalangeal joint. It may start as an induration in the skin or as a small scaling nodule, the skin of which may be thin, dry, and parchment-like, or may be hypertrophic with grey or rosy-red papillae surrounded by dilated capillaries. Later this nodule develops and breaks down, and may form an exuberant cauliflower-like mass with an irregular, granular, and ulcerous surface, which grows and encroaches on the surrounding skin and invades the deeper structures such as muscle, tendons and bone. Involvement of the lymph glands, which is frequent, occurs later, often after two or three years. Pain may be severe from local pressure and from direct invasion of the nerve trunks, or spread to the axillary glands, involving the brachial plexus. Destruction of the muscles and tendons leads to functional loss, and toxic symptoms develop. Metastases (usually in the lungs and liver) occur late. Surgical treatment is the method of choice. In the case of isolated carcinomas the incision depends on the extent of involvement; superficial carcinomas may be widely excised without the removal of tendons or bones. In cases of deep ulcers and large cauliflower growths, portions of the hand may sometimes be preserved. Carcinomas of the nail-bed are especially malignant and require the amputation of the finger. In the

give his close personal attention to the statements that had been presented to him by the deputation.

SIR ROBERT PHILIP'S paper entitled "The principles underlying a scheme of anti-tuberculosis measures in any country" has been reprinted from the *Transactions* of the fourteenth annual conference of the National Association for the Prevention of Tuberculosis, by direction of the council.

Medicine.

56. Non-diabetic Glycosuria.

W. B. MEYER (*Med. Welt*, May 4th, 1929, p. 637) sums up the diagnostic points in differentiating glycosuria due to a true diabetes from that associated with other conditions. Diabetic glycosuria is characterized as follows: it is directly dependent on the amount of carbohydrate intake; has a definite limit of tolerance; can be diminished or even removed by insulin; is accompanied by hyperglycaemia; and is manifested by a characteristic blood sugar curve. Non-diabetic glycosuria may be caused experimentally by stimulation of the floor of the fourth ventricle and by injection of adrenaline; such glycosuria is transitory and is not accompanied by the symptoms which arise after removal of the pancreas. Pathological conditions in man which may cause a similar transitory glycosuria include any organic cerebral disturbance, such as trauma, tumour, or haemorrhage; the glycosuria is more or less independent of the carbohydrate intake and shows no evidence of disturbed metabolism. To this group belongs the glycosuria caused by drugs and toxins, such as strychnine, morphine, chloroform, and fevers, which damage the central nervous system. Regarding endocrine glycosurias, that of hyperthyroidism is caused by increased suprarenal secretion. In acromegaly the position is peculiar, as there is possibly a connexion between the hormones of the pituitary and the pancreas; no appreciable damage is caused, dietetic treatment is unnecessary, and insulin would not affect the cause. In the preceding conditions the etiology is more or less clear; as regards the next group, however—renal glycosuria—opinions are divided, but it may be defined as a faulty condition of the kidney itself, the general metabolism being unaltered. The signs appear after the injection of phloridzin, and the glycosuria of pregnancy is also comparable. Frank states that every pregnant woman has a latent renal diabetes; even if sugar is excreted only in very small quantities these women are subject to a high degree of acidosis. Actual treatment is not necessary, but an excess of sweets should be avoided; insulin, as in glycosuria innocens, has no effect. This last-named condition is important diagnostically; it occurs at all ages, gives rise to no symptoms, and is often discovered accidentally during an examination for life insurance. Its differential diagnosis from true diabetes is therefore of great importance. There are four points characteristic of it: the amount of glycosuria is almost independent of the carbohydrate intake; there is no limit of tolerance; insulin does not diminish or stop the glycosuria; in most cases the blood sugar is normal and the curve rises and falls sharply. There is an intermediate group of cases usually showing a high blood sugar figure, with its characteristic symptoms resembling true diabetes but uninfluenced by insulin. Such cases are possibly responsible for the so-called failure of insulin therapy. Regarding prognosis, glycosuria innocens is regarded as a developmental failure, and it does not predispose to diabetes. The intermediate group cannot be regarded so favourably with any certainty; it requires treatment by diet and insulin to control the symptoms.

57. Aphasic and Monoplegic Migraine.

L. MORENAS and J. DECHAUME (*Journ. de Méd. de Lyon*, April 20th, 1929, p. 259) discuss the connexion between migraine and epilepsy. Although it is rare, Charcot and other authorities have described a paretic type of migraine with or without aphasia. The authors record the case of a man, aged 66, who had had attacks of migraine complicated by aphasia, paraesthesia, convulsions of a Jacksonian type, and transient brachial monoplegia. The first attack occurred when the patient was 22 years old and was in the army. The whole left arm was involved, formication and cramps being succeeded by epileptiform convulsions and paralysis of the limb; this lasted for a few hours and was accompanied by severe headache, followed by mucous vomiting, which relieved all the symptoms. No further attack occurred for twelve years, but since the age of 34 they have recurred every two or three months. The patient's blood yielded a negative Wassermann reaction, and there was no history of syphilis. Two children suffered from nervous disorders, one son being an epileptic. The patient suffered from bradycardia, abnormal variations in blood pressure, and vasomotor disturbances, all pointing to vago-sympathetic imbalance. The alkalinity of the blood was increased. For some days before his death the patient exhibited signs of mental deficiency, with partial right hemiplegia, paralysis of the sphincters, and transient aphasia. The hemiplegia and aphasia disappeared for a time and he became excited and violent; this was follow[illegible]ening coma and right hemiparesis. [illegible]s signs were absent. The patient died in coma; his last illness was of seven days' duration. The necropsy revealed only punctiform haemorrhages resembling those which are found in experimental shock. The authors think that these facts constitute clinical and anatomical proofs of the vasomotor origin of the symptoms of migraine. They claim to have established an etiological link between migraine and epilepsy, and exhibit this case as a transitional type between those two syndromes.

58. Transient Hemiplegia.

E. KAUFMANN (*Deut. med. Woch.*, February 1st, 1929, p. 184) reports a case of transient hemiplegic attacks in a man aged 62, and discusses the etiology of this condition. His patient began with symptoms of vertigo, cardiac irregularity, and occasional sensations of impending death. There was some evidence of involvement with the peripheral circulation, including pallor, and marked variations of the blood pressure from time to time. A diagnosis was made of commencing aortic sclerosis, and treatment with hypertonic medicaments was continued for four months with some little improvement. A sudden acute attack then occurred, the patient became gravely collapsed, with a thread-like pulse, the rate being 60. There was evidence of slight hemiparesis on the right side of the body and face, together with an increasing motor aphasia. The tendon and bone reflexes were briskly increased on the right side, but the signs of Babinski and Oppenheim were absent and there was no ankle clonus; the left side was normal. Remedies for shock, such as coramine, were administered without effect, but the intravenous injection of hexatone—a water-soluble form of camphor—brought about marked improvement. The author discusses the production of such fleeting localized cerebral symptoms, and comes to the conclusion that in his case there was sufficient evidence of arterial degeneration, together with a possibility of involvement of the lenticulostriate artery, which is known to be one of the commonest sites of endarteritis. The involvement of the neighbouring basal ganglia and the failure of the pyramidal reflexes is thereby explained.

Surgery.

59. Carcinoma of the Hand.

M. L. MASON (*Arch. of Surg.*, May, 1929, p. 2107) reports a series of 25 cases of carcinoma, pre-carcinomatous ulcers, and *x*-ray dermatitis, and defines four main groups of carcinoma of the hand: (1) those appearing as the result of trauma or irritation or on the basis of a scar; (2) those arising from a previous growth, such as a wart or naevus; (3) carcinomas developing *de novo* from the previously unchanged skin; and (4) a group in which the data are too meagre for classification. The carcinoma usually appears on the dorsum of the hand, and rarely on the palm or volar surfaces of the fingers; *x*-ray carcinoma is always on the dorsum of the hand and usually on the left. Carcinomas arising on the hand have a long chronic course; in the pre-ulcerative stage a small tumour may appear over a metacarpo-phalangeal joint. It may start as an induration in the skin or as a small scaling nodule, the skin of which may be thin, dry, and parchment-like, or may be hypertrophic with grey or rosy-red papillae surrounded by dilated capillaries. Later this nodule develops and breaks down, and may form an exuberant cauliflower-like mass with an irregular, granular, and ulcerous surface, which grows and encroaches on the surrounding skin and invades the deeper structures such as muscle, tendons and bone. Involvement of the lymph glands, which is frequent, occurs later, often after two or three years. Pain may be severe from local pressure and from direct invasion of the nerve trunks, or spread to the axillary glands, involving the brachial plexus. Destruction of the muscles and tendons leads to functional loss, and toxic symptoms develop. Metastases (usually in the lungs and liver) occur late. Surgical treatment is the method of choice. In the case of isolated carcinomas the incision depends on the extent of involvement; superficial carcinomas may be widely excised without the removal of tendons or bones. In cases of deep ulcers and large cauliflower growths, portions of the hand may sometimes be preserved. Carcinomas of the nail-bed are especially malignant and require the amputation of the finger. In the

case of carcinoma arising from *x*-ray dermatitis it is imperative that all keratotic spots should be excised regardless of their extent. The prognosis for carcinoma of the hand is relatively favourable, as the slow growth makes the lesion less to be feared, but the tendency for multiple growth must be kept in mind. There was a favourable result in 65 per cent. of the cases under review.

60. Pruritus Ani.

J. F. MONTAGUE (*Amer. Journ. of Surg.*, April, 1929, p. 475) states that, from his experience of 391 cases of pruritus ani, he has found that every case is definitely curable. He considers that the use of *x*-ray treatment should be avoided, and that ultra-violet or quartz light therapy often causes an aggravation and extension of the pruritus. The use of carbolic acid ointment and belladonna or cocaine suppositories he also deprecates, and avoids giving opium suppositories and morphine owing to the danger of habit formation in a chronic ailment. Every patient should undergo a complete physical examination, to include the entire anal canal, rectum, and sigmoid, and also a blood chemistry and urine analysis. It has sometimes been found that incorrect diet has been responsible for the intestinal causes of the pruritus. In order to give relief from the persistent and distressing itching and to give the patient rest and sleep the undercutting operation is performed. This consists of the severing of the sensory nerves immediately under the skin in the perianal region by means of a pair of double-edged dissecting scissors under a local anaesthetic. This operation gives the skin sufficient sensory rest for it to heal, and in early cases the same result may be obtained by cauterizing with a 10 per cent. aqueous solution of silver nitrate the sensory nerve endings which have been exposed by scratching in the pruritic area. Protective ointments such as vaseline, boric ointment, or zinc oxide ointment may then be used. Vaccines, especially the pruritus vaccine of Lederle, are useful in minimizing the low-grade dermal infection which is often present in these cases.

61. Tuberculous Adenitis of the Cheek.

A. V. RODRIGUEZ (*La med. Ibera*, May 25th, 1929, p. 683), who records two illustrative cases, states that this form of adenitis originates in dental cavities which become infected by the tubercle bacillus, though its presence is not always easy to demonstrate. Adenitis of the cheek has been classified by Lenormand into three groups: (1) an upper or molar group, situated over the upper jaw or malar bone (uncommon); (2) a middle or buccinator group, situated on a line running from the labial commissure to the lobe of the ear; and (3) a lower or maxillary group, formed by two or three glands situated on the outer surface of the lower jaw in front of the masseter muscle. Tuberculous adenitis of the cheek must be distinguished from inflammatory processes of the lips, cheeks, and alae nasi, which may give rise to infections of the glands, as well as from mycosis, sporotrichosis, osteomyelitis of the jaw, and gummata. Ultra-violet rays, which possess a strong bactericidal power as well as an intense biological and biochemical action, have a remarkable effect on these tuberculous lesions, and generally by the third or fourth sitting the appearance of the lesion completely changes, owing to cessation of the suppuration and inflammation. The scar remaining is less visible than with any other treatment, such as the galvano-cautery or chemotherapy.

62. Difficulties in Appendicectomy.

H. B. DEVINE (*Journ. Coll. of Surg. of Australasia*, March, 1929, p. 375) is of the opinion that appendicectomy may be one of the most difficult and responsible of operations, and that a complete knowledge of the anomalous appendix and of the requisite surgical technique is necessary. The sources of difficulty are various. One may be the particular stage of the inflammatory process—thus, for example, the appendix may lie in the wall of the abscess. In such conditions it is wise not to look for the appendix but for the ileo-caecal junction, which may be easily found by following along a piece of free ileum nearest to the mass; the base of the appendix usually lies an inch below and an inch posterior to this point. An appendicectomy may be difficult because resistant fibrosis has taken place in a partially cured appendicitis, rendering the peritoneal tissue planes almost inseparable. Devine thinks it is sometimes wiser to leave such an appendix alone and to operate six months later, when these adhesions will have been absorbed. An appendix situated in an abnormal position through a developmental error is a frequent cause of dangerous symptoms and of difficult operation. The development of the appendix is described, and three important misplacements are discussed—the subhepatic, pelvic, and retroperitoneal. Chronic appendicitis in the subhepatic region is confused with chronic cholecystitis; *x*-ray localization may be impossible, and tenderness, caused by dragging on the caecum, may be the only differential diagnostic point. An upper paramedian incision is best for this type of appendicitis. Pelvic appendicitis presents such a variety of symptoms that diagnosis is often difficult. Some of these are enumerated, and the operation advocated is fully described. Retroperitoneal or retrocaecal appendicitis presents peculiar diagnostic difficulties. Generally there is some form of obscure abdominal pain; it may be in the right loin or in the vicinity of the gall-bladder, with disease of which it is often confused. Localization by *x* rays may fail, and this, with the anomalous symptoms, may be evidence that a retroperitoneal appendix is present. There may be no tender point and no reflex rigidity, especially in fat people. A split-muscle McBurney incision, as in pelvic appendicitis, is most suitable.

Therapeutics.

63. Treatment of Pernicious Anaemia.

P. VÉRAN (*Rev. de Méd.*, 1929, No. 3, p. 325) fears lest the brilliant results of the liver treatment of pernicious anaemia may cause other measures to be neglected, notably insulin therapy and blood transfusion, which are of great practical importance and have their own indications. A historical review of liver treatment is given; its preparation, dosage, indications for its employment, and the results following its use are described. In the plastic (cryptogenetic) type of pernicious anaemia no treatment can compare with that of liver. Two hypotheses have been advanced as to its action—namely, that it neutralizes haemolytic poisons of probably intestinal origin, or that it specifically supplies the deficiency of an unknown chemical agent. If, on careful examination, the anaemia is found not to be merely symptomatic and curable by an etiological treatment, Véran at once gives daily 200 to 250 grams of boiled or raw calves' liver, prepared according to one of the methods described. If the patient is very weak or anorexic, very nauseated or diarrhoeic, hepatic extract should first be given in such doses as to establish toleration for natural liver. The diet, which need not be rigorously calculated, should be simple, varied, and substantial, rich in vitamins and poor in carbohydrates. Large doses of hydrochloric acid (8 c.cm. of a 10 per cent. solution in 350 grams of lemonade) and ergosterol in infantile cases is given, but no other medication. In cases of slow blood regeneration, hepatic extract should be added to the liver diet and the method of Walinski be employed. This consists in the injection twice daily of 5 to 10 units of insulin, combined with weekly blood transfusions of 250 to 300 grams. A patient, though apparently cured, should continue to take daily a maintenance dose of liver, based on regular blood examinations; in order to avoid satiation, the extract may be alternated with the natural liver and some days of rest be allowed between courses of treatment. In aplastic anaemia liver therapy has always proved to be inefficacious.

64. Thymus Extract in Fragilitas Ossium.

E. GORTER (*Nederl. Tijdschr. v. Geneesk.*, April 27th, 1929, p. 2022) records two illustrative cases in children, aged 1½ and 2 years respectively, suffering from fragilitas ossium and rickets. The latter condition was cured by the ordinary antirachitic treatment, which did not have any effect on the fragilitas ossium. Rapid recovery, however, followed administration of thymus gland capsules. Enriquez and Robuski, as well as Goldner, have found that in fractures the thymus gland presents signs of hyperfunction, shown by a more rapid and complete evolution of all the thymus elements and the absence of all signs of involution. It is particularly in the early stages of the fracture that the signs of regeneration are evident, while after the fracture has been consolidated the thymus becomes normal again. Gorter suggests that in his cases there was a thymus insufficiency, and that the lack of thymus hormones was the cause of the fragilitas ossium. He adds that it would be desirable to investigate the question whether a patient with uncomplicated osteopsathyrosis, or even with osteogenesis imperfecta, would also derive distinct benefit from the administration of thymus extract.

65. Danger of Excessive Doses of Vitamin D.

L. J. HARRIS and T. MOORE (*Biochem. Journ.*, vol. xxiii, No. 2, p. 261) submit evidence supporting the view that the excessive administration of vitamin D induces *per se* a condition of specific hypervitaminosis, quite apart from any possible ill effects due to any poisonous by-products, if such exist. They found that when radiostol (activated in oil) and irradiated ergosterol (activated in alcohol) were given as foods, the high vitamin D dosage being the same in each

case, they produced hypervitaminoses of the same degree of severity. Ergosterol, when irradiated in the absence of any solvent, also produced specific ill effects. Details are given of their experiments which showed that the toxicity of irradiated ergosterol disappeared concurrently with the destruction of vitamin D by over-irradiation, and that non-irradiated ergosterol, and ergosterol which had been resinized without the production of vitamin D, were both non-toxic. The pathological conditions so induced included large deposits of calcium in the heart muscle and the kidneys; the formation of urinary calculi also appears to have been facilitated, and in this connexion reference is made to the paper of Dixon and Hoyle in the *British Medical Journal* (1928, vol. ii, p. 832). The authors suggest that there is an optimum dosage for vitamin D; underdosage and overdosage cause respectively deficient and excessive figures of the blood phosphorus and/or blood calcium, with consequent calcification. The atrophy of the thymus gland and spleen which may be thus provoked are contrasted with the enlargement or hypertrophy often seen in clinical rickets. The evil consequences of excessive vitamin administration seemed to be more marked in earlier life.

Laryngology and Otology.

65. Disease of the Middle Turbinate.

GRAIN (*Rev. de Méd.*, 1929, No. 2, p. 217) defines three clinical varieties of the ethmoidal disease of Bosworth: hypertrophy of the mucosa, with or without degeneration; osseous hypertrophy of the middle turbinate, simple or complicated with mucosal degeneration, which may be localized or generalized over the ethmoid; and ethmoidal suppurations. He discusses the first two groups and describes their anatomical pathology. Hypertrophy of the bone takes the form of a cystic or ampullar dilatation. In uncomplicated types the disease is unaccompanied by nasal symptoms, and the most prominent symptom is headache. The pain, localized exclusively to the corresponding hemicranium, is felt especially in the frontal, parietal, and orbital regions; it is constantly present, and does not respond to treatment with sedatives and hypnotics. These three characteristics easily distinguish the headache from other cephalalgias. Accessory symptoms are variable appetite, general asthenia, insomnia, inaptitude for work, and ocular fatigue, especially marked on the side of the lesion. Permanent compression of the terminal filaments of the spheno-palatine nerve, which supplies the middle turbinate, causes an irritation or excitation that is transmitted to the centres of the fifth and sixth pairs and of the sympathetic; thus the triple characters of the headache are produced. Besides this ampullar dilatation, other causes of the pain may be polypoid degeneration, high deviation of the septum, and the presence of a bony irritative spine of the septum. Treatment is solely surgical, and resection of the ethmoidal head or of the bony spine is the method of choice. Attention should also be paid to the inferior turbinate if necessary. The headache and other symptoms immediately and definitely disappear on removal of the cause. A case of ampullar dilatation together with its treatment is reported.

67. Tuberculous Otitis Media.

G. H. COX and J. G. DWYER (*Arch. of Otolaryngol.*, April, 1929, p. 414) comment on the frequent occurrence of tuberculosis of the middle ear, especially in children of school age, and place the incidence as high as 15 per cent. of all cases of purulent otitis media. They state that the condition is occasionally primary, but most often secondary to tuberculosis of some other structure, usually a tuberculous gland. The infection may be carried by the Eustachian tube or by the blood stream. A blood-borne infection, however, usually affects the mastoid process primarily and alone. The authors describe two types of aural tuberculosis. The first consists of cases of chronic otitis media which give no typical signs and are only discovered to be tuberculous on bacteriological examination of the discharge. The second type of case begins insidiously without the pain and rise of temperature usually associated with otitis media. If these patients are seen early small tubercles may be discovered on the membrane, and a small perforation which rapidly increases in size is common. Facial nerve paralysis frequently accompanies tuberculous otitis media, and the ear may become completely deaf from involvement of the labyrinth. Tuberculous meningitis is a complication to be feared; it occurs in 5 per cent. of the reported cases. Tuberculous mastoiditis heals slowly and is associated with the formation of small sequestra. The authors have treated their cases by exposure of the middle ear to sunlight (either real or artificial) by means of a special apparatus, and the instillation of alcohol drops into the middle ear. They have also used injections of tuberculin in some of their cases, with good results. Great importance is attached to the bovine type of tubercle bacillus in the pathology of these cases, and the bacteriological examination of the milk which the child is receiving is advised.

68. The Treatment of Chronic Otorrhoea.

I. HARNICK (*Canadian Med. Assoc. Journ.*, May, 1929, p. 503) states that chronic otorrhoea takes its origin from an acute otitis media, and, after discussing the causes leading to the persistence of the inflammation and the development of the chronic process, concludes that chronic infection, excessive formation of granulations, osteitis, and tubal disturbances are the leading factors in maintaining a chronic aural discharge. Treatment must be directed to the removal of these causes, and the best medicament in this condition is Calot's mixture, which is of the following composition: *guaiacol* 1 part, *creosote* 5, *sulphuric ether* 30, *iodoform* 10, and olive oil 70 parts. The guaiacol and creosote have a caustic action upon the granulations in addition to their antiseptic properties; the iodoform is an excellent antiseptic and cicatrizant; and the ether, by dissolving the fatty components of the discharge, allows a more intimate contact of the solution with the diseased tissue. When applying the treatment the ear should first be cleansed of all secretions. After carefully shaking the bottle, 5 to 10 drops of the mixture are instilled into the affected aural canal, the head being so inclined that the treated ear is uppermost, and in order to get the fluid into the Eustachian tube tragus massage is employed. This procedure is carried out every night for a week. By this time the character of the secretion will have changed, and when it is markedly reduced in amount the Calot's solution is discontinued and insufflations of boric acid are used. In cases which do not rapidly improve, granulations may need treatment with silver nitrate (60 per cent.), aural polyps may need snaring off, or surgical intervention on the nasopharynx may be necessary. Harnick believes that Calot's solution is exceedingly efficacious in properly selected cases of otorrhoea, and should be tried before deciding on a radical operation. It is of little value in cases complicated by cholesteatoma, and in those on the basis of lues, diabetes, local malignancy, or actinomycosis.

Obstetrics and Gynaecology.

69. Dangers of Pituitary Extract in Obstetrics.

A. M. MENDENHALL (*Journ. Amer. Med. Assoc.*, April 20th, 1929, p. 1341) emphasizes the dangers attending the use of pituitary extract in labour, and states that there is no dependable way of knowing the degree of its effect that may be expected. Different extracts, and even two ampoules of the same extract, may vary widely in their effects, and, in addition, marked idiosyncrasies to this drug have been noted. These two factors render impossible the fixing of a safe dose. The action of pituitary extract often begins within four minutes after its injection, and may continue from twenty to thirty minutes without intermission. It produces a tonicity of the uterus that is often extreme and uninterrupted for many minutes, and among the results reported from its use is uterine rupture. The action may be so violent as to produce serious injury to mother or child, and, since there is no satisfactory antidote, it is a very dangerous drug. Mendenhall considers pituitary extract valuable in post-partum haemorrhage; it is probably safe in the third stage of labour, and in induction if used cautiously and in properly chosen cases. It is never safe in the first stage of labour, and rarely, if ever, in the second; other obstetrical procedures are nearly always safer. While no definite rule can be made as to the treatment of ruptured uterus, Mendenhall believes that the conservative treatment of packing from below may save many patients when more radical measures may prove fatal. Should laparotomy be performed, the rent, if not too large and irregular, may be repaired; this, however, increases the risk of a future labour. For this reason, and also because of the possibility of reducing sepsis, hysterectomy is often preferable.

70. Avertin Anaesthesia in Gynaecology.

ACCORDING to H. GROSSMANN (*Zentralbl. f. Gynäk.*, March 30th, 1929, p. 780) avertin is a safe basal narcotic if full anaesthesia is avoided, and the action of the drug is assisted by careful preparation of the patient and, when necessary, by the addition of ether. The use of a solution of avertin in amylene hydrate, 1 c.cm. of the solution containing 1 gram of avertin, is said to mark a distinct advance; amylene hydrate has a hypnotic action intermediate in intensity between that of chloral hydrate and paraldehyde. This avertin solution was

effective in doses of 0.1 gram per kilogram of body weight, as compared with 0.15 gram of avertin; about one-third of the patients required ether in addition. The maximum dose of avertin used was 8 grams, and, because of the relative frequency in them of asphyxial attacks, persons aged under 22, or weighing less than 45 kilograms, are unsuitable subjects. Major vaginal and abdominal gynaecological operations of all kinds have been performed under avertin narcosis; two deaths have followed in a series of 300 cases reported by the author.

71. Puerperal Inversion of Uterus.

L. E. PHANEUF (*Surg., Gynecol. and Obstet.*, May, 1929, p. 709) records three cases of complete inversion of the uterus; in one the condition was acute and in the other two it was chronic. In the acute case the inversion occurred with the delivery of the placenta; the organ was replaced manually under ether, the resulting shock being treated by hypodermoclysis of salt solution. The puerperium was uneventful and recovery was complete. In the two chronic cases, one of which had existed for thirty-four days and the other for two and a half months, anterior colpo-hysterotomy (Spinelli's operation) was performed, with eventual recovery. Phaneuf states that the condition is rare in occurrence. Its predisposing causes bring uterine inertia, pressure above the fundus, and traction on the cord. Severe shock is the main symptom, and should this occur after the third stage of labour uterine inversion should be borne in mind. When the occurrence is acute, treatment consists of manual reduction when possible, or, otherwise, laparotomy, and reposition by taxis. Chronic cases are best treated by anterior colpo-hysterotomy when it is possible for the uterus to be saved, or by vaginal hysterectomy when this is impossible. Before attempting any operative procedure shock must be treated by blood transfusion. The author considers that the obstetrical future after Spinelli's operation should be similar to that following Caesarean section.

72. Torsion of the Ovary during Pregnancy.

R. BERNARD (*Soc. Nat. de Chir.*, May 18th, 1929, p. 651) reports an unusual case of a twisted ovary in a woman who had been pregnant for six weeks. She complained of pain in the right side, and as this was most severe over McBurney's point, and was accompanied by vomiting and an elevated temperature, a diagnosis of appendicitis was made. This pain subsided, but reappeared in the lumbar region; it was later localized in the bladder, suggesting the possibility of cholecystitis or infection of the urinary system. Further examination showed an absence of rigidity of the abdominal wall, and it was possible to feel a hard mass, about the size of an orange, to the right of the pouch of Douglas. This mass was painful to the touch, mobile, and separated from the uterus, which was enlarged to a size corresponding with the time of pregnancy. A diagnosis of extrauterine pregnancy was therefore made, and an operation disclosed, to the front and right of a gravid uterus, a small dark tumour; the pedicle of this was about as thick as the little finger, and was composed of utero-ovarian vessels which were coming from the pelvis. The Fallopian tube was normal and healthy, and situated in front of the tumour. The ovary and tube were removed, and it was found that the tumour was solid and appeared, not as an ovarian cyst, but as a normal ovary enlarged by interstitial oedema. Recovery was uninterrupted and pregnancy followed the normal course.

73. Gastro-Intestinal Symptoms of the Climacteric.

J. M. G. GALVÁN (*Rev. Med. Latino-Americana*, March, 1929, p. 649) discusses the digestive disturbances caused by the climacteric, and states that when it is spontaneous the symptoms are generally less violent than those associated with a climacteric due to an accident or to surgical operation. The date of onset of the climacteric ranges between the ages of 30 and 50. Galván classifies the resulting phenomena by defining the following three groups. (1) The gastric climacteric, of which the symptoms fall into the four sub-groups of gastric neurosis, functional dyspepsias, haemorrhages, and organic lesions such as ulcer and cancer. (2) The intestinal climacteric, which may appear in the five different forms of stenosis, diarrhoea, colitis (especially the muco-membranous type), haemorrhoids, and melaena. (3) The hepatic [illegible] climacteric, in which the symptoms fall into the four groups of cholecystitis and cholelithiasis, [illegible], jaundice, and diabetes.

74. Peritonization after Hysterectomy.

GUYOT and MORIN (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, March, 1929, p. 218) describe a method of peritonization which can be used in the operation of hysterectomy. This method is particularly applicable to cases where the pedicles are long and the peritoneum is consequently abundant. By means of a catgut stitch the layer of peritoneum over the posterior surface of the cervix is approximated to the vesical peritoneum on the anterior cervical wall in the mid-line. On either side of this stitch a purse-string suture is used to invaginate the ends of the round and infundibulo-pelvic ligaments and, at the same time, to bring together the anterior and posterior edges of peritoneum. The authors claim that the advantages gained by adopting this procedure are that it is easily and rapidly performed; that the area liable to become adherent subsequent to operation is lessened; and that the portion of the cervix remaining is prevented from prolapsing.

Pathology.

75. Malignant Embryonic Nephroma.

G. FORNI (*Arch. Ital. de Chir.*, April, 1929, p. 411) reports a case of renal tumour in a boy 3 years old. The child was somewhat restless, but otherwise his health had been normal. The hypochondrium and left flank were notably distended, and the subcutaneous venules over this area were very evident. Palpation revealed a rounded mass in the left hypochondrium, which was smooth, somewhat hard, not fluctuating, and about the size of a foetal head; its position changed with the respiratory movements. Nephrectomy was performed, and, in spite of the large size of the tumour, no difficulties were experienced; the patient's recovery was without incident. The tumour was found to arise from the convexity of the kidney, both poles and hilum being concerned; it weighed 500 grams. Growth had been so rapid that in a few months the presence of a tumour was obvious to the mother, and its weight was between one-quarter and one-third of that of the child. Microscopically the neoplasm presented a varied structure. Part consisted of masses of round cells of medium size, separated by bundles of spindle-shaped cells; both cell types had an immature appearance. Another part of the tumour was composed of tubules of various calibre with round lumina, and a capillary formation resembling the structure of an embryonic glomerulus. Portions of the growth were myxosarcomatous. Between the tumour and the renal cortex there was a stratum of fibrous connective tissue. After discussing the various types of renal tumours found in children, Forni agrees with other observers that an adenosarcoma appears to be derived from the mesonephros, but he concludes that the name "malignant embryonic nephroma" (Trappe) applies to the tumour he describes.

76. Cultivation of Tubercle Bacilli.

SINCE guinea-pig inoculation is both costly and slow, H. J. CORPER and N. UYEI (*Journ. Lab. and Clin. Med.*, February, 1929, p. 393) have devised a special method for the identification of tubercle bacilli when these are present in small numbers in sputum, urine, or tissues. In order to destroy contaminating organisms the tuberculous material is incubated with an equal volume of 6 per cent. sulphuric or 3 per cent. hydrochloric acid, intimate contact being secured by centrifuging. They have obtained good results by subsequently planting the deposit on a medium comprising potato (autoclaved and subsequently ground), agar, glycerol, and crystal violet. A good growth of tubercle bacilli appears in from two to five weeks. The authors state that tests have proved this medium to be superior to that of Petroff, and as good as guinea-pig inoculation from the practical clinical standpoint. The amount of glycerol employed (1 to 5 per cent.) has no appreciable influence on the growth of the tubercle bacilli.

77. Effect of Lipoids on Resistance to Infection.

H. REITER (*Zeit. f. Immun. u. exp. Therap.*, May 6th, 1929, p. 433) records some experiments on the resistance of mice fed on different dietaries to mouse typhoid infection. The control animals were given bread, oats, and water; the experimental animals received milk instead of water, or dried testicle, lecithin, or cholesterol in place of the oats. Infection was achieved by giving 1/1,000th or 1/2,000th of a culture by an oesophageal sound. The results showed that, judging by the expectation of life in days (apparently up to 19 days), the figures were 75 per cent. higher for the mice fed on milk, 68 per cent. for those fed on dried testis, 38 per cent. for those fed on lecithin, and 54 per cent. for those fed on cholesterol. In a previous paper the author found that mice inoculated subcutaneously with dead mouse typhoid bacilli developed a higher agglutination titre when fed on a lipoid-containing diet than similar mice fed on a lipoid-free diet. He considers, therefore, that the presence of lipoid in the food has a beneficial effect on the resistance to infection.

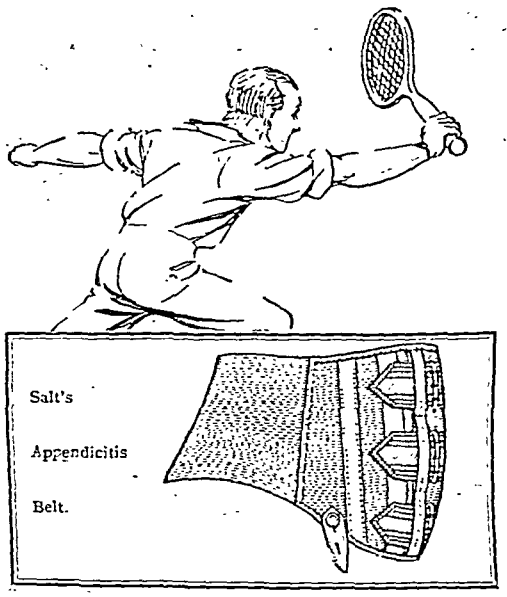
SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

Salt's specially light Appliances for SUMMER WEAR



Outdoor exercise during the summer months demands a seasonal change in the type of appliance worn just as much as in clothing.

Salt's specially light Appliances for Summer Wear

provide a lightness (while ensuring proper support) that affords complete freedom in bodily movement.

Apart, however, from such a consideration are the questions of economy and personal cleanliness, the wearing of a Salt's summer appliance enabling the patient to release the ordinary appliance for the necessary cleaning and repairing.

GAMAGES, HOLBORN, LONDON, E.C.1

GAS IN THE HOSPITAL

As well as being the most hygienic form of HEATING, gas is the most easily regulated, the cleanest and the most dependable. That is why gas fires are used on so large a scale in Hospitals and Nursing Homes.

Gas is almost universally employed for COOKING purposes in the Hospitals of this country. It provides good and economical meals. Cooking is simplified and dirt eliminated.

In the LABORATORY gas is invaluable for all the many processes requiring a reliable and easily-controlled heat.

For STERILISATION of instruments and bed-clothes, and for INCINERATION of wads and swabs, gas apparatus is supplied, and used extensively.

For WATER-HEATING and all LAUNDRY WORK, including drying and ironing, gas is indispensable.

GAS BRINGS HEALTH

For free information on the use of gas in hospitals, and for expert advice and help, write to the Secretary at the address below.

THE BRITISH COMMERCIAL GAS ASSOCIATION, 28, GROSVENOR GARDENS, LONDON, S.W.1

In Treating Movable or Floating Kidney

You are cordially invited to visit STAND No. 98 B.M.A. EXHIBITION MANCHESTER July 22nd to July 26th

Proper Abdominal Support Is of the Greatest Service

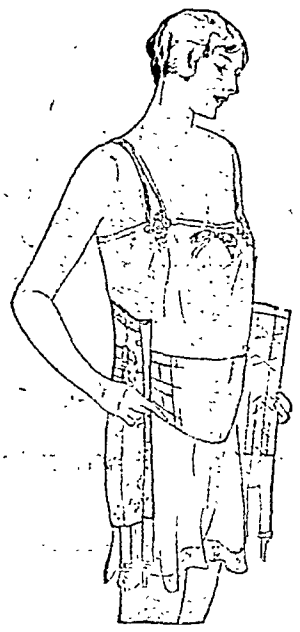
An abdominal support, to be of aid in treating movable or floating kidney, should, it is agreed, support the abdomen from below, upward and backward. It should fit snugly. It should reach from the pubic bone to the umbilicus.

The Spencer abdominal belt and supporting corset meet these requirements with absolute perfection.

Each garment is designed from complete body measurements and figure description to meet the individual requirements of the patient who will wear it.

The Spencer support for movable or floating kidney is adjusted over each hip by a series of tapes and self-locking buckles.

The patient can readily adjust a Spencer support alone, except in unusual cases.



SPENCER SUPPORTING CORSET
Front opened and held back to show inner supporting section

The support should be applied with the patient recumbent, pelvis raised, knees drawn up.

Usually, the support itself, used in co-ordination with the regimen prescribed by the physician, will give relief without pads. Pads will, however, be provided with the support when the physician prescribes them.

The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

We issue the following booklets on the use of Spencer Supports: Sacro-iliac Strain, Hernia, Enteroptosis and Intestinal Stasis, Movable Kidney, Pregnancy and Postpartum Support. We will gladly send you any of them in which you are interested.

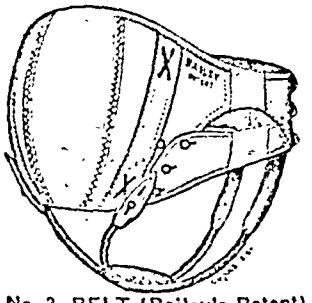
SPECIAL BELT FOR AFTER COLOSTOMY.



No. 3. BELT (Bailey's Patent)
for PROLAPSUS UTERI.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

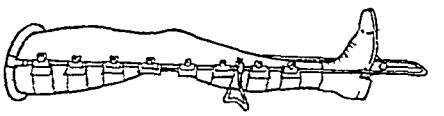
COLLENDER'S SPLINTS

(Patented in many Countries)

Combine the advantages of the Thomas Splint with many improvements and additions.



They are supplied in fitted cases. The larger set provides material for treating ten fractures simultaneously.

Advantages:

They ensure accurate extension and safe transport. They are adjustable to any length of limb. All parts are interchangeable, standardised, numbered, and replaceable. Being made of metal—Duralumin—they combine great strength with very light weight. They are untarnishable, and can be immersed in sterilizing fluid without injury. They can be used repeatedly.

Invaluable for

Hospital Emergency work, particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

Hard and grass tennis courts, 18-hole putting course, rowing, bathing, shooting, riding. Sulphur spring in grounds. An ideal home for those who want a sporting and peaceful holiday away from the crowd.

Write for illustrated Tariff. Special terms for the medical profession. C. BANZHAF, Proprietor.

HARTMANN'S ZINKOCOLL RUBBER ADHESIVE PLASTER

Durable—Non-Irritating—Adhesive.

Manufactured by Paul Hartmann, Württemberg.

Hartmann's Plasters are made of specially prepared rubber from which the irritating oils, resins and acids have been removed, the rubber being combined with pure oxide of zinc.

Hartmann's Adhesive Plaster "Zinkocoll" is instantly adhesive without the aid of heat or moisture, and remains exactly where placed. It is perfectly flexible, conforming to any part of the body.

Hartmann's "Zinkocoll" is not affected by heat, cold or moisture, and can be applied to the most delicate skin without causing irritation.

Hartmann's "Zinkocoll" is absolutely durable and unchanging even in tropical climates.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMEAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

Applications are invited for the post of PROFESSOR OF CLINICAL PATHOLOGY.

The salary offered is £E.1,500 (about £1,530) a year without pension, and the appointment will be on contract for five years, but may be renewed by mutual consent for a further period.

The Professor of Clinical Pathology will be expected to organize the work of the Department of Clinical Pathology in its relation to the Kasr el-Aini Hospital and to give such courses of instruction as may be decided upon. Preference will be given to candidates possessing a special knowledge of diseases of warm climates. The appointment is to be a full time post, no private practice being allowed.

An allowance equal to one month's salary will be paid on arrival at Cairo for travelling expenses.

Applications, accompanied by testimonials and references, to be addressed to the Dean, Faculty of Medicine, Egyptian University, Cairo, so as to be received not later than September 15th, 1929

British Red Cross Society's CLINIC FOR TREATMENT OF RHEUMATIC DISEASES, PARK SQUARE EAST, REGENT'S PARK.

There is a vacancy for the post of MEDICAL SUPERINTENDENT (Non-resident). It is hoped that the building will be ready for patients by November 1st next, but the duties of the Medical Superintendent will begin in September, as he will be expected to help in the preparation for the reception of patients, who will be Out-patients only. After the Clinic is opened his duties will be to see that treatment prescribed by the staff is properly carried out and to supervise the general administration of the Clinic. Applications may be accompanied by not more than two testimonials (copies). Salary £600 a year payable quarterly. The initial appointment will be for one year, but may be renewable.

Applications to be sent to the Secretary of the Clinic Committee, British Red Cross Society, 19, Berkeley Street, London, W.1, not later than July 24th next.

Salop County Council.

MEDICAL INSPECTION OF SCHOOL CHILDREN AND MATERNITY AND CHILD WELFARE.

Applications are invited from registered medical practitioners (male) for the post of Assistant Medical Officer to work under these Schemes. Salary £600 per annum, rising by annual increments of £25 to a maximum of £700, with travelling and out-of-pocket expenses on a fixed scale.

The salary will be subject to a deduction of 5 per cent. for superannuation under the Local Government and Other Officers Superannuation Act, 1922, and the candidate selected will be required to pass a medical examination

Candidates must possess a Diploma in Public Health, and experience in Refraction work will be *considered an important* additional qualification

Applications should be received on or before Saturday, July 27th, by the County Medical Officer of Health, College Hill House, Shrewsbury, from whom forms of application, conditions of appointment, list of duties, and any other information can be obtained.

County Borough of Croydon.

CROYDON MENTAL HOSPITAL, UPPER WARLINGHAM, SURREY.

APPOINTMENT OF SECOND ASSISTANT MEDICAL OFFICER.

The Visiting Committee of the Croydon Mental Hospital are prepared to receive applications from medical men for the appointment of *Second Assistant Medical Officer* at the Croydon Mental Hospital. No married quarters are provided.

The salary will be at the rate of £350 per annum, rising by annual increments of £25 each to a maximum of £450 per annum, and the age of the candidate should not exceed 35.

Furnished apartments will be provided, with board and washing, and for the purpose of Superannuation will be valued at £150 per annum.

Candidates must be registered under the Medical Act, and *preference will be given to* those candidates who have held the post of House Surgeon or House Physician at a General Hospital.

The appointment will be subject to the provisions of the Asylum Officers Superannuation Act, 1909.

Applications to be made on forms to be obtained by sending a stamped addressed foolscap envelope to the undersigned, with copies (not originals) of not more than three testimonials of recent date, not later than 11 o'clock in the forenoon of Thursday, August 8th, endorsed "Croydon Mental Hospital, Second Assistant Medical Officer."

Canvassing in any form is prohibited.

Town Hall, Croydon. July 17th, 1929. JOHN M. NEWNHAM, Clerk to the Visiting Committee.

City of Manchester.

APPOINTMENT OF ASSISTANT TUBERCULOSIS OFFICER.

The Public Health Committee invites applications for the position of Assistant Tuberculosis Officer at a commencing salary of £650 per annum, rising by annual increments of £25 to £750 per annum. (First increment January 1st, 1931.)

Candidates must be fully qualified Medical Practitioners having special knowledge of Medical and Surgical Tuberculosis. Candidates should state whether they possess the Diploma of Public Health.

Applications, stating age, qualifications, and experience, with copies of not more than three recent testimonials, and endorsed on the envelope "Assistant Tuberculosis Officer," must be addressed to the Town Clerk only, and not to members of the Committee or Council, and must be received by him not later than Monday, July 29th.

The gentleman appointed will be under the administrative control of the Medical Officer of Health and the immediate control of the Senior Tuberculosis Officer. He will be required to devote the whole of his time to the duties of his position, to execute the Deed of Service, and to contribute to the Corporation Superannuation Fund.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order, F. E. WARBRECK HOWELL, Town Clerk.

Town Hall, Manchester. July, 1929.

Poplar Board of Guardians.

APPOINTMENT OF ASSISTANT MEDICAL OFFICERS.

The Guardians of the above-named Parish hereby give notice that they will, at their meeting to be held on August 28th next, proceed to the appointment of Three Assistant Medical Officers at the St. Andrew's Hospital, Devons Road, Bow, E.3, each at a basic salary of £228 p.a., rising by two instalments to £254, thence by one instalment to £260, together with bonus in accordance with the Civil Service Award, producing at present a total commencing salary of £350, with board, lodging, and washing. The persons appointed will be required to carry out such duties as may be required of them by the Medical Superintendent of the Hospital or the Guardians.

Special consideration will be given to candidates who hold qualifications and have had experience in up-to-date Maternity work.

Forms of application may be obtained from the Clerk to the Guardians, 45, Upper North St., Poplar, E.14, and must be returned, with copies of not more than three recent testimonials, not later than first post Saturday, July 27th.

By Order, G. BUTLER, Clerk to the Guardians.

Clerk's Office, 45, Upper North St., Poplar, E.14.

City and Port of Plymouth.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified medical men for the post of Assistant Medical Officer of Health to the City and Port of Plymouth.

Applicants should not be more than 35 years of age, and must possess a Diploma in Public Health, or a qualification in State Medicine, or a Diploma in Tropical Medicine.

The person appointed will be required to assist the Port Medical Officer from time to time as required, and he will also assist in the general public health work of the City and in the various sub-departments of the Public Health Department. He will be required to act under the general supervision of the Medical Officer of Health and to carry out any duties delegated to him from time to time.

The salary will be at the rate of £600 per annum, and the appointment will be terminable by three months' notice on either side.

Forms of application are not provided, and applicants should send a statement of their professional qualifications and experience, together with copies of not more than three recent testimonials, to the undersigned on or before Saturday, August 24th. Canvassing will disqualify the applicant.

Envelopes must be endorsed "Assistant Medical Officer of Health."

A. T. NANKIVELL,

APPOINTMENT OF MEDICAL SUPERINTENDENT.

Applications are invited for the post of Medical Superintendent at the Mental Deficiency Institution shortly to be opened at Coleshill Hall, about 10 miles from Birmingham.

Candidates must be fully qualified registered medical practitioners, and have had experience in institutions for mental defectives.

Commencing salary £700 p.a. and emoluments (including house, fuel, lighting, and laundry) valued at £200 for superannuation purposes. The appointment will be subject to three months' notice on either side, and the selected candidate will be required to join the Asylums and Certified Institutions (Officers Pensions) Act, 1918.

Applications, stating age, medical qualifications, and experience, accompanied by copies of not more than three recent testimonials, endorsed "Medical Supt., Coleshill Hall," should be addressed to the undersigned not later than August 22nd.

Canvassing will be deemed a disqualification.

F. H. C. WILTSHIRE,
Town Clerk.

Council House,
Birmingham

West Derby Union.

RESIDENT ASSISTANT MEDICAL OFFICER (Male).

The Guardians invite applications for the above position at the MILL ROAD INFIRMARY, EVERTON, LIVERPOOL, at a salary after the rate of £200 per annum, together with rations, apartments, etc.

Candidates must be single, fully qualified, and registered.

Appointment will be for a period of one year in the first instance, subject to one month's notice to terminate on either side at any time, and to extension for a further period of twelve months at the option of the Guardians.

Applications to be sent, stating age, qualifications, etc., with copies of three recent testimonials, to the undersigned not later than first post on Tuesday, August 6th.

J. CHARLES McGRATH.

County Hall,
Wakefield. July 10th, 1929.

Birmingham Union.

ERDINGTON HOUSE.

RESIDENT ASSISTANT MEDICAL OFFICER (Female).

Applications are invited from fully qualified medical practitioners for the above appointment at the Erdington House. The Institution accommodates 1,800 inmates, of whom approximately 800 are mental patients of varying types, and 250 are sick, the remainder being aged and infirm, ordinary house cases, etc. Parts of the Institution are certified under the provisions of the Mental Deficiency Acts, 1913 to 1927.

The person appointed will be required to assist in the general medical work of the Institution and to undertake such other duties as may be assigned to her by the Guardians or the Medical Officer, and, should occasion arise, to assist at any other Institutions under the control of the Guardians.

The minimum and maximum of the scale of salary attached to the appointment are £250 and £350 per annum respectively, and the salary of the successful candidate will be fixed within these limits according to qualifications and experience. In addition, full residential emoluments (rations, apartments, laundry, and attendance) will be provided. A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers' Superannuation Act, 1896, and for this purpose emoluments are valued at £200 per annum.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded so as to reach me not later than July 29th.

Canvassing the Guardians, directly or indirectly, will disqualify.

C. P. BEECH,
Clerk to the Guardians.

Union Offices,
Edmund Street,
Birmingham. July 13th, 1929.

City of Plymouth.

UDAL TORRE SANATORIUM, YELVERTON.

RESIDENT MEDICAL OFFICER.

Applications are invited from duly qualified and registered practitioners (male) for the post of Resident Medical Officer at Udal Torre Sanatorium (39 beds). The Sanatorium is situated on Dartmoor about 9 miles from Plymouth, and is reserved for the treatment of intermediate and advanced cases of pulmonary tuberculosis in male persons.

The salary will be at the rate of £450 per annum, together with board, residence, and laundry. Quarters are not provided for a married man. The appointment will be terminable by three months' notice on either side. Canvassing will be a disqualification.

The person appointed will rank as an Assistant Medical Officer of Health, and will be required to act under the general supervision of the Medical Officer of Health and to carry out any duties delegated to him from time to time.

Forms of application will not be provided, but candidates must state their age and experience.

Applications, together with copies of not more than three recent testimonials, must be delivered to the undersigned at his office on or before Saturday, August 24th, and envelopes must be endorsed "Resident Medical Officer."

A. T. NANKIVELL,
Medical Officer of Health.

Town Hall,
Stonehouse,
July 15th, 1929.

City of Nottingham Education Committee.

Applications are invited from duly qualified and registered medical practitioners for the post of SENIOR ASSISTANT SCHOOL MEDICAL OFFICER.

The salary scale for the post will be £600 p.a., rising, upon approved service, by annual increments of £25 to £800 p.a. The Committee will, in fixing the commencing salary, take into consideration any special qualifications and experience of the selected candidate.

Applications, which should be made on the special forms obtainable from the undersigned, must be returned by August 30th.

Canvassing, either directly or indirectly, will be deemed a disqualification.

A. H. WHIPPLE,
Director of
Education.

School Medical Service,

Nottingham.

Wanted at the Plymouth Poor Law Institution, a Resident Locum Tenens for four weeks from August 5th. Particulars of remuneration, etc., may be obtained upon application to W. H. Davy, Clerk to the Guardians, Poor Law Offices, Greenbank Road, Plymouth.

Salisbury Municipality

MEDICAL OFFICER OF HEALTH.

Applications are invited for the position of Medical Officer of Health to the Salisbury Municipality, at a salary of £900 per annum.

Applicants must possess the Diploma of Public Health.

Duties will include those prescribed by the Local Government Board (England) for Medical Officers of Health and, in addition, the medical examination of natives in the Municipal Area; attendance on natives at the Lazaretto; and European patients at the Isolation Hospital.

The officer appointed will be the administrative head of the Sanitary and Public Health Department.

Applicants must state age, and whether single or married, submit qualifications and present occupation, together with three testimonials.

Applications close on August 31st, and must be addressed to the undersigned, endorsed "M.O.H." on the cover.

The successful applicant will be required to assume duties as soon as possible after October 15th. No travelling expenses will be paid, but salary will commence from date of leaving to take up duties.

By Order of the Council,
R. L. POLLETT,
Town Clerk.

Town House, Salisbury, S. RHODESIA.
June 25th, 1929.

The Royal Infirmary, Sheffield.

(500 Beds.)

OPEN APPOINTMENTS.

The Weekly Board of Management invite applications for the four undermentioned posts:

ASSISTANT CASUALTY OFFICER,
HOUSE SURGEON,
OPHTHALMIC HOUSE SURGEON, and
ASSISTANT OPHTHALMIC HOUSE SURGEON.

The appointments will be tenable for six months from July 1st. The salary attached to each appointment is £80 per annum, with board and residence. Applications, with copies of testimonials, to be sent to the undersigned immediately.

JNO. W. BARNES, F.C.I.S.,
General Superintendent and Secretary.

Board Room, June 19th, 1929.

The Royal Infirmary, Sheffield.

OPEN ELECTION.

A vacancy having arisen in the post of SURGICAL REGISTRAR to the Royal Infirmary, Sheffield, the Weekly Board invite applications therefor.

Candidates must be Fellows of one of the Colleges, and the successful candidate will not be allowed to engage in general practice. The post is tenable for one year, and the holder will be eligible for re-election. The salary is £200 per annum.

Applications, stating age and qualifications, together with copies of testimonials, to be sent to the undersigned immediately.

JNO. W. BARNES, F.C.I.S.,
General Superintendent and Secretary.

Board Room, June 19th, 1929.

The General Hospital, Birmingham.

Applications are invited for the post of SECOND ASSISTANT VISITING ANÆSTHETIST.

The successful candidate will be required to attend on three mornings a week from 9.30 to 1, and will be paid an honorarium of £50 per annum.

Applicants, who must be registered medical practitioners, and have had experience in the administration of anæsthetics, should send in their applications to the undersigned, with copies of testimonials, by July 22nd.

A. H. LEANEY, House Governor.

The Miller General Hospital, Greenwich Road, S.E.10.

HONORARY PHYSICIAN TO THE SKIN DEPARTMENT.

The Board of Management invite applications for the above post. Candidates must be Fellows or Members of the Royal College of Physicians of London and not engaged in general practice, and they will be expected to call upon the Members of the Honorary Medical and Surgical staff, a list of whom can be obtained from the Secretary.

Applications, together with copies of three recent testimonials, should be sent to the Chairman of the Hospital as soon as possible.

July 16th, 1929.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in July, 1929. Applications should reach the War Office not later than July 20th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of July. They must be under 28 years of age on August 1st, 1929, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—Pay from £500 to £2,000 a year according to rank and length of service.

Gratuities on Retirement.—After 7 years' service £1,000.
„ 15 „ „ £2,800.
„ 18 „ „ £3,500.

Current rates of retired pay range from £372 per annum normally earned by a Major after 20 years' service to £940 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.1), Whitehall, London, S.W.1.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One *half* of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in July to make nominations, and the selected candidates will be required to attend a course of instruction commencing on the 6th August, 1929.

Devonshire Hospital, Buxton,
DERBYSHIRE. (300 Beds.)
(A Special Hospital for Rheumatism and Allied Diseases.)

ASSISTANT HOUSE PHYSICIAN.

The Committee invite applications for this post. To commence duties August 1st. The successful candidate will be engaged for a period of not less than six months. The appointment is not open to ladies. Salary commencing £150 per annum, rising to £175 after three months' service, with furnished apartments, board (excepting stimulants), and laundry. Applications, with copies of three recent testimonials, endorsed "Assistant House Physician," to be sent in at once. The Medical Staff consists of eight Honorary Physicians, an Honorary Surgeon, a Bacteriologist, a Radiologist, a Biochemist, and two Resident House Physicians. The Hospital contains a Pathological Laboratory, and X-ray Department. This appointment offers special facilities for anyone preparing a thesis or wishing to do research work.

Canvassing will disqualify.

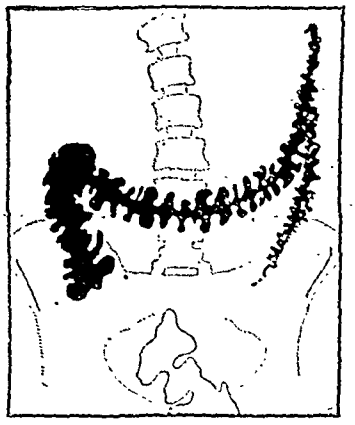
Fees 5/- to 21/-. Only about 10 midwiferies at from 3 to 10 gns. Very good house with 4 reception, 6 bedrooms, usual offices. Garden. Large garage. Price for freehold £3,000, half on mortgage. Premium 2½ years' purchase.
7. SURREY.—HOSPITAL TOWN.—PARTNERSHIP.—A one-fourth share (to commence) in an old-established good mixed Practice. Average gross cash receipts £4,400, including panel of 2,000 and appts. worth £500 p.a. Fees 5/6 to 21/-. Suitable house. Premium 2 years' purchase. Purchaser should be about 30 years of age and a good surgeon.
8. NEAR HARROGATE.—UNOPPOSED COUNTRY PRACTICE.—Income for last year over £500, but has done about £1,500. Visits and medicine 3/6 to 10/6. Little midwifery. Large house in 7½ acres of ground. Excellent sport of all kinds. Price, freehold, £2,000. Premium, including drugs, etc., £550.
9. NEAR BATH.—Old-established unopposed country PRACTICE, held by Vendor 10 years, and situated in an attractive district within easy reach of two good towns. Cash receipts for 1928 £656, and this year at rate of £700. Panel of over 500. Fees 2/6 to 12/6. Large house with 6 bedrooms, etc., and an acre of garden and paddock. Price for freehold £1,200. Premium £900.
10. KENT.—COAST TOWN.—Well-established mainly industrial PRACTICE. Steady average income of over £1,560. Panel of 1,350. Advice and medicine mainly 5/- and 5/6, a few at 7/6. Visits and medicine 5/6 to 7/6, a few at 15/- and 21/-. Convenient house, with 5 bedrooms, on lease (9 years), rent £100 p.a. Premium 1½ years' purchase.
11. CHANNEL ISLANDS.—Old-established better and middle-class PRACTICE. Income about £1,000, but has been much more. Fees 5/- to 21/-. Little midwifery. Large well-situated house freehold. Excellent schools and sport. Good hospital. Practice very easily worked. Price for house and Practice £4,000.
12. BLACKPOOL.—Well-established better and middle-class PRACTICE. Income last year over £1,200. Panel of 556. Fees from 2/6 to 4/-. Little midwifery. Good house in quiet residential district. Price, freehold, £2,700. Premium 1½ years' purchase, £1,000 cash and balance by instalments.
13. LIVERPOOL.—Mixed-class PRACTICE, producing this year at the rate of over £1,200. Panel of 560. Good house specially built and well situated, containing 2 reception, 4 bedrooms, etc. Large garden. Garage. Price for leasehold £1,800, part on mortgage. Prem. £1,650.
14. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non panel general and surgical Practice can be acquired by a suitable qualified man possessing the F.R.C.S. Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation, at present held on lease with option to purchase. Premium 2 years' purchase.
15. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, near good town.—Well-established Practice, averaging over £1,000 p.a., including panel of nearly 600. Fees 2/6 to 10/-. Excellently situated house, with 2 reception, 5 bedrooms, etc., and separate entrance to professional rooms. Good garden and garage for 2 cars. Can be rented on lease at £100 p.a. Premium £1,300.
16. PARTNERSHIP, with ultimate succession.—SOUTH-WEST LONDON.—A third or half share, to commence with, in an old-established good mixed non-panel Practice, offering large scope. Receipts for last year nearly £2,300. Fees 2/6 to 7/6. Little midwifery. Good house, with garden. Can be obtained on long lease at the very moderate rent of £55 p.a. Premium 2 years' purchase.
17. CARDIFF.—Good-class old-established non-dispensing PRACTICE, worth last year about £1,570, including select panel of 450. Visits up to 21/-. Very little midwifery. Good house in best part of City, with ample accommodation. Price, free hold, £2,000. Prem. £2,000.
18. MIDLANDS.—Country District near large Town.—Agricultural and working-class PRACTICE, rapidly increasing. Income last year £1,250, including panel of 945. Visits 3/6 and 5/-. Small convenient house, with large garden and garage. Price (freehold (including all furniture excepting linen and plate) £1,650 (£1,000 on mortgage at 4 per cent.) Excellent sport. Premium £1,800.
19. SOUTHAMPTON.—Very good mixed-class PRACTICE, averaging over £1,550 p.a., including panel and transferable appts. worth about £800. Visits 3/6 to 10/6. Particularly nice house, in quiet road, with ample accommodation and good garden. Price £1,950 (freehold £1,250 on mortgage. Premium 1½ years' purchase, or near offer.
20. EAST COAST.—SEAPORT TOWN.—Old-established mixed and working-class PRACTICE. Average cash receipts for the past three years £1,835, including panel of over 1,000. Fees 2/6 to 10/6. Midwifery has been discouraged, but much can be had at fees from 5 gns. upwards. Good house with 2 reception, 5 bedrooms, etc. Electric light. Small garden. Price for freehold £1,350, part on mortgage. Premium 1½ years' purchase, part by instals. Ill health reason for sale.
21. SOUTH CORNWALL.—COAST TOWN.—PARTNERSHIP.—A one-fifth share in an old-established Practice, producing about £3,000 p.a., including panel of nearly 2,400. Very good house, with 2 reception, 5 bedrooms, etc., and usual offices. Rent on lease £45 p.a. Well-equipped Hospital. Premium 2 years' purchase.
22. SUSSEX COAST TOWN.—Old-established and increasing PRACTICE producing last year nearly £1,600, and this year at the rate of over £2,000. Panel of 1,150. Visits from 3/6. Eight-roomed house, with usual offices and garden. Price for freehold £1,450, £1,000 on mortgage. Premium 1½ years' purchase.
23. YORKS.—PROSPEROUS LARGE TOWN.—Well-established compact PRACTICE, averaging nearly £1,600 p.a., including panel of 1,400. Fees 5/- upwards. Not much midwifery. Low expenses. Very well-situated double-fronted house, 2 reception, 4 bedrooms, etc., and good professional rooms. Garden. Price for freehold £1,500 (£1,000 on mortgage). Premium 1½ years' purchase.
24. EAST COAST.—ASSISTANTSHIP with view to PARTNERSHIP.—A one-third share in a very sound mixed-class Practice, producing £2,300 p.a., and offering excellent scope. Panel of about 1,000, and good appointments. Choice of houses. Premium 2 years' purchase.
25. MANCHESTER.—PRACTICE is situated in a growing district offering very good scope. Income for the immediate past 12 months over £1,600, including panel of nearly 900. Fees 5/6 upwards. Detached well-situated house, with 3 reception, 5 bedrooms, etc. Can be rented on lease at £110 p.a. Premium 1½ years' purchase.
26. WEST END.—Good-class non-panel and non-dispensing PRACTICE established many years. Average cash receipts for past three years nearly £1,400. Fees one guinea. Suitable accommodation available. Premium £2,000. Good introduction. Ill health reason for sale.
27. EASTERN SUBURB.—PARTNERSHIP, with succession.—A half-share in an old-established Practice averaging over £1,100 p.a., including panel of 1,145. No midwifery, but scope for this. Suitable house, with electric light and garden. Price £800. Premium 2 years' purchase.
28. EASTERN COUNTIES.—Unopposed Country PRACTICE, easily worked, and situated in beautiful district, near two good towns. Average cash receipts for past three years £1,064, including panel of 650. Nice house, with 3 reception, 6 bedrooms, etc. Price for freehold £2,000. Premium £1,500.
29. LONDON.—EAST END.—Increasing cash and panel PRACTICE producing £450 p.a., including 300 panel patients. Visits 5/- upwards. Very little Midwifery. Seven-roomed house on lease. Rent £78, inclusive of rates and taxes. Premium £650.
30. WITHIN 50 MILES OF LONDON.—In a small Country Town, in pretty district, a well-established increasing PRACTICE, worth last year over £800, including panel of 525, and appts. about £60. Visits 5/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (5 reception, 5 bedrooms, etc.), with large garden. Tennis court. Garage. Electric light. Price for freehold £3,100. Premium 1½ years' purchase. Exceptionally good educational facilities for boys.
31. LONDON, NORTH.—RESIDENTIAL SUBURB.—Good middle-class PRACTICE. Income for last year over £700, with ample scope. Small select panel of nearly 300. Fees 2/6, 3/6, and 5/-. No midwifery. Excellent detached corner house, with electric light. Garden. Garage. Price for leasehold (75 years) £1,750. Premium 1½ years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

Occult Constipation



Occult constipation (from an X-Ray) 24 hours after opaque barium meal. There has been one small stool as usual. Note the deep haustrations and partial dilatation of the cæcum.

THE menace of occult constipation lies in the fact that the patient may have regular daily evacuations, and is therefore unaware of the constant retention of fæcal matter, which may ultimately form a hard and deep coating on the intestinal wall, leaving but a small passage through which painful and partial evacuation takes place.

When headaches, lassitude, and the conditions usually associated with the development of intestinal toxæmia lead to the suspicion of hidden constipation, the reliance of many physicians is on AGAROL Brand Compound, *the original mineral oil and agar-agar emulsion.* Combining lubrication with softening of the fæcal mass and gentle peristaltic stimulation, AGAROL Brand Compound is particularly indicated in cases of occult constipation — because of its positive, yet gentle action, without habit formation.

A generous trial quantity sent on request

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

AGAROL Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion and has these special advantages:
Perfectly homogenized and stable: pleasant taste without artificial flavouring; freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage; no griping or pain; no nausea or gastric disturbances; not habit forming.

AMENORRHEA
DYSMENORRHEA

"It is a very great mistake to treat amenorrhea as though it were simply a lack of the catamenia, for it is a great deal more than that. Behind this lack lies a cause. It may be in the uterus or the ovaries, or it may be still farther back in the secretions of the endocrine glands or in the functioning of the vegetative nervous system."—("The Treatment of Amenorrhea," Dalché, *Revue Française de Gynecologie et d'Obstetrique*, May 1, 1920.)

In the treatment of irregularities of the catamenia, rational therapeutic procedure is directed to the restoration of normal balance in the endocrine and vegetative nervous systems.

Hormotone
BRAND

contains thyroid, pituitary, adrenal, and gonad substance, combined to take advantage of the demonstrated synergism existing between them. In the treatment of these disorders Hormotone has been very successful.

Dose: One or two tablets three times daily.

DIABETES AND AUTO-TOXINS

Though the introduction of Insulin is one of the great events of substitution-therapeutics, both the incidence and the mortality of diabetes remain at levels incompatible with the notion that a truly curative agent has been found. Diet and the effective elimination of normal and abnormal auto-toxins still demand the attention of the clinician, every bit as much as in pre-insulin days. It is peculiarly important in diabetes, with its abnormal blood-chemistry and general functional dysbalance, to secure the easy, complete, and regular removal of intestinal residues. It is one of the oldest of observations that any degree of constipation aggravates the diabetic condition.

Mild salines, which do not irritate the intestinal lining, acting solely through their power of retaining fluid according to osmotic law, stimulating peristalsis in a natural way by mere bulk, are usually the laxatives to be preferred; but owing to the nausea and discomfort produced by the mineral sulphates, and the even greater harm in diabetes caused by the disguising of these salts with sugar and flavouring agents, most saline preparations are rightly regarded with disfavour.

It has been found, however, that in Eno's "Fruit Salt" is available to diabetic patients an effective saline laxative, entirely free from the unpleasant mineral salts, and with no trace of sugar or added flavour. A teaspoonful of Eno in a glass of water is a refreshing effervescent drink with an agreeable taste, due solely to its own composition and texture.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

MEDICAL ANNUAL, 1929

A YEAR-BOOK OF TREATMENT AND PRACTITIONER'S INDEX. A Review of the World's Progress in Medicine and Surgery, arranged in Alphabetical order for easy Consultation.

"Contains a thoroughgoing survey, valuable alike to the general practitioner, the specialist, and the laboratory worker, of the progress of medicine and the ancillary sciences in Europe and America during the past twelve months."—B.M.J. *"Stands alone in British medical literature."*—LANCET.

Bristol: JOHN WRIGHT & SONS Ltd. [*New Illustrated Catalogue Free.*] London: SIMPKIN MARSHALL Ltd.

METHODS AND USES OF

HYPNOSIS AND SELF-HYPNOSIS.

By Bernard Hollander, M.D. 6s.

Dr. Hollander's new book is the result of thirty years' experience of experimental hypnosis and hypnotic treatment, and contains directions how to apply hypnotism for the treatment of functional nervous and mental disorders and moral failings, as well as a survey of all that is scientifically known of this form of psychotherapy.

THE ENDOCRINES IN GENERAL MEDICINE

W. LANGDON BROWN, M.A., M.D., F.R.C.P. (Physician to St. Bartholomew's Hospital. 7s. 6d. net.

"The combination of early physiological work, clinical experience, and wide reading has enabled Dr. W. Langdon Brown to write a clear and philosophical handbook full of suggestive ideas on this difficult subject. Attractive from its potentialities and therefore open to rash speculation in the armchair, the therapeutic use of endocrine preparations is much in need of such an authoritative and well-considered opinion."—*Extract* BRITISH MEDICAL JOURNAL.

HEART DISEASE IN CHILDHOOD

H. B. RUSSELL, M.D., M.R.C.P.(Lond.), and C. K. J. HAMILTON, B.M.(Oxon), M.R.C.P.(Lond.) 7s. 6d. net.

This subject opens up a very extensive field, and in order to keep this volume within reasonable bounds the authors have limited themselves to a discussion of the essentials only of the disease. A chapter has been devoted to the consideration of rheumatism; and the symptoms of, and treatment for, acute rheumatic pericarditis, endocarditis, myocarditis, and congenital heart disease are dealt with in a way such as will commend itself to the practitioner. A chapter on the electrocardiograph and its application and uses is included.

"The authors have treated their subject in a lucid and most able manner, discussing the problems with which every practitioner has to contend, and explaining methods of diagnosis and treatment."—MEDICAL TIDES.

HEALTHY WINDOWS FOR THE SICK ROOM

Unchecked Passage of Ultra-Violet Rays through "Vita" Glass

Natural ultra-violet radiation can penetrate to rooms through "Vita" Glass windows. Ordinary glass acts as a shutter to the ultra-violet rays; it bars them out.

"Vita" Glass, the only British window glass of its kind, gives a permanent passage to the ultra-violet rays. After a short period of exposure to daylight, its power of transmission is stabilised, and a "Vita" Glass window operates as a health measure every daylight hour, summer or winter, whether the window faces north, south, east or west.

Already nearly 200 hospitals and over 100 schools are equipped with it, as well as numerous factories, offices and private houses. "Vita" Glass is not an expensive measure to prescribe for patients of modest means. For example, a bay-window of average size can be fitted with "Vita" Glass for 38/-, plus the cost of fixing.

Further information about "Vita" Glass will be sent to any Medical man who is interested. Write to: "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

Local Anæsthesia in Surgical Practice

CANCER OF THE GREATER CURVATURE OF THE STOMACH.

Typical Case.

Operation: Gastric Resection.

D. E., aged 60 years.

Technique of Anæsthesia: Local infiltration and anterior splanchnic. A transverse infiltration across both recti was made, using 150 c.c. of a 0.5 per cent. Novocain-Adrenaline solution. The abdomen was opened with perfect negative pressure and a large tumour in the great curvature presented in the incision. The lesser omentum was infiltrated with Novocain-Adrenaline solution and divided. After a thorough examination of the liver, which revealed no signs of metastasis, it was decided that the case was probably operable. The retro-peritoneal space, which was exposed after dividing the gastro-hepatic omentum, was carefully infiltrated with Novocain-Adrenaline solution. The duodenum was then divided between clamps beyond Hartmann's lines. This manœuvre was also painless. The jejunum was anastomosed to the lower portion of the gastric incision, the remainder of which was closed with linen. The patient's pulse was 74 at the completion of the operation, with no change in his colour or general condition except that he was tired. The operation required one hour and thirty minutes. His recovery was uneventful.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full particulars of this and one hundred other operations under Local Anæsthesia will be found in above work, published by Henry Kimpton, 263, High Holborn, W.C.1.)

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (*Pinus silvestris, Abies alba, Pinus montana*) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

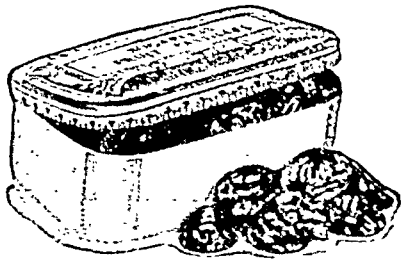
The 'Allenburys' *Sugarless Fruit* PASTILLES

One

Flavour

only



At the request of several physicians a notable addition has been made to the well-known series of 'Allenburys' Pastilles. This is a pastille with a delightful fruit flavour yet entirely free from sugar. It is specially designed for diabetics and others on a restricted carbohydrate régime and can be eaten freely without harmful effect. The 'Allenburys' Sugarless Pastille maintains the high standard of excellence associated with the 'Allenburys' products and can be recommended to patients with confidence.

In tins containing 4 ozs. and 1 lb.

ALLEN & HANBURYS Ltd.
37 Lombard Street, London, E.C. 3.

OVALTINE

BEFORE AND AFTER OPERATION

As a diet preparatory to surgical operation "Ovaltine" possesses unique advantages. It tends to keep the metabolism of the patient as nearly normal as possible. It also avoids a long period of starvation prior to operation, consequent irritation of the stomach by the gastric flow, and predisposition to greater irritation from the anæsthetic.

"Ovaltine" provides a means of nourishing the patient three or four hours before operation. It is almost completely absorbed, and therefore the stomach and intestines are empty at the time the operation is conducted.

"Ovaltine" lessens the predisposition to shock and counteracts the tendency to acidosis common after chloroform and ether anæsthetics.

In the usual processes of post-operative feeding by easy stages, from sips of water to the regular diet, "Ovaltine," by reason of its delightful palatability, ready digestibility, and high nourishing power, is ideally adapted.

A liberal supply for clinical trial sent free on request.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

Produces normal functioning of the entire glandular system

COMPOSITION. Protonuclein is the pioneer organo-therapeutic product, and the popularity it enjoys to-day, a quarter of a century after its introduction to the medical profession, speaks eloquently for the sound reasoning that was responsible for its inception. Protonuclein is a true pluri-glandular product, consisting of a physiological association of those glandular structures particularly rich in nuclear material, namely the Thyroid, Thymus, Spleen, Pancreas, Stomach, Salivary Lymphatics and Brain (including the Pineal and Pituitary).

INDICATIONS. Protonuclein restores, regulates and augments the activity of glands or organs of the internal secretory system that may be apathetic, deficient or deranged.

FORMS. Protonuclein is issued to the Medical profession in tablets. Bottles of 100, 500 and 1000. Stocked by all first-class Pharmacists.

Samples and Descriptive Literature from Sole Distributing Agents for U.K. and Irish Free State: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

Action of Antiseptics on Organic Salts

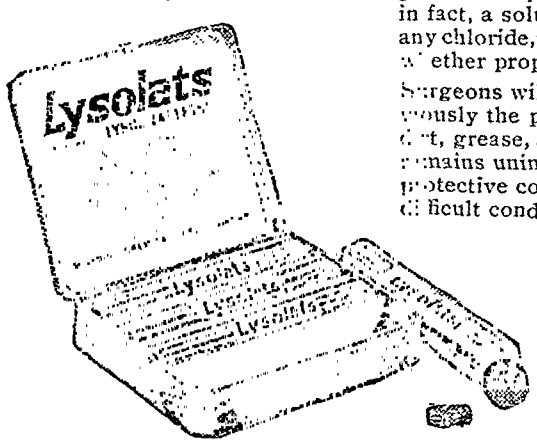
Important Findings

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney St., London, S.E.1

One of the problems of antiseptic practice has been the rapid deterioration of emulsified disinfectants on contact with organic matter. As doctors know only too well, the salts break up the emulsion, throw out the active principle of the antiseptic, and destroy its bactericidal value.

Experiments with 10% solutions of many lysols and other disinfectants in wide use have revealed that Lysolat alone preserves a perfect emulsion in salt solutions and in sea water; in fact, a solution of 3% sodium chloride, or for that matter any chloride, would destroy any other cresylic acid preparation, whether proprietary or otherwise.

Surgeons will realise the significance of these tests, for obviously the physical action of the antiseptic in disintegrating dirt, grease, and blood clots, and attacking the bacteria within, remains unimpaired. Lysolat is specially sensitised with a protective colloid, which preserves its efficacy under the most difficult conditions encountered by the surgeon or the chemist.



Lysolats

PATENT 118667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

Non-Caustic
Palatable

CREMO-CARBONATES presents certain unique features which warrant its preference whenever an antacid and corrective is indicated. For the first time the well-known protectives and antacids, bismuth, magnesia, and lime, are supplied as a suspension of particles of colloidal dimensions.

Its colloidal nature gives it maximum covering power superior to that of a mere mechanical mixture of bismuth, magnesium, and calcium.

CREMO-CARBONATES is a soothing, antacid corrective and digestant, particularly useful in the treatment of hyperacidity accompanied by flatulence and of any other conditions where there is excessive secretion of the gastric juices.

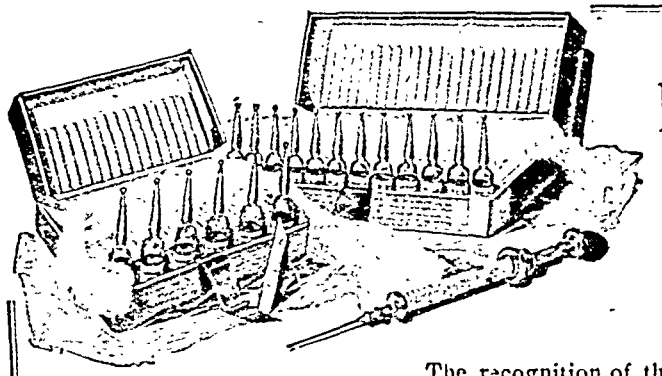
RH



Pituitary
(Posterior Lobe)
Extract
B.D.H.

Issued also in boxes containing 100 ampoules specially for hospital use

The recognition of the value in medical practice of glandular products has been followed by the realisation of the necessity for their accurate standardisation.

Recent research confirms the need for the stringent double standardisation (the effects upon the contraction of uterine muscle and upon the blood pressure respectively) to which every batch of Pituitary (Posterior Lobe) Extract B.D.H. has always been submitted since it was first issued to the medical profession.

Pituitary (Posterior Lobe) Extract B.D.H. is an entirely British product; it is made in the B.D.H. laboratories from carefully dissected glands. The scientific methods of manufacture and standardisation of this preparation ensure its uniformity of activity and efficacy of therapeutic effect.

TOXINS
and
Arterio-Sclerosis

The great change that has been brought about in the treatment of arterio-sclerosis and certain other circulatory diseases through the widespread conviction that—as pointed out by Bishop*—

"The vast majority of cases as they occur in adult life are due to the indirect influence of intestinal putrefaction upon the blood vessels and nervous tissue"

is of more than passing interest to the medical practitioner, now that we have a really efficient non-toxic intestinal bactericide that can be administered with the certainty that it will not only destroy the causal agents of the putrefaction referred to by Bishop, but will do so without absorption or toxic action.

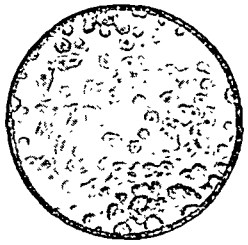
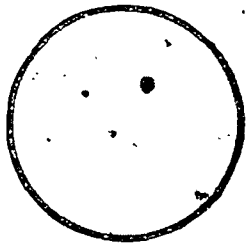
CHLOR-SAN

REG.D

GERMICIDAL TESTS



Photograph 1



Photograph 2

These reproductions of photo-micrographs demonstrate effectively the strong germicidal properties of Chlor-San. Photograph 1 shows the result of treating a fæces suspension for 20 minutes with a 2% solution of Phenol, and quite clearly shows the bacteria which had not been destroyed.

Photograph 2 shows the result of treating a similar suspension for the same period with a 2% solution of Chlor-San, and very clearly indicates the total destruction of bacteria.

CHLOR-SAN IS A SCIENTIFIC GERMICIDE WHICH BELONGS TO THE CLASS OF DISINFECTANTS CONTAINING CHLORINE IN THE FORM OF HYPOCHLORITE. UNDER CERTAIN CONDITIONS IT LIBERATES NASCENT CHLORINE, AND IN THIS WAY EXERCISES A POWERFUL BUT PERFECTLY SAFE DEODORANT, DISINFECTANT, AND PURIFYING ACTION. ALTHOUGH POSSESSING SUCH POWERFUL ANTISEPTIC AND GERM-KILLING PROPERTIES, CHLOR-SAN IS NON-POISONOUS AND IS FREE FROM THE DANGERS OF FLUIDS WHICH CONTAIN CARBOLIC ACID AND CRESOL.

CHLOR-SAN IS THE IDEAL ANTISEPTIC FOR THE HOME: FOR USE AS A MOUTH-WASH OR GARGLE, AS A NASAL DOUCHE, FOR THE BATH, FOR THE SICK ROOM, AND FOR CLEANSING ARTIFICIAL TEETH

The FEEDING of PREMATURE INFANTS.

The successful nourishment of the premature infant calls for the very best efforts on the part of everyone concerned. Relatively speaking, a large amount of food is required, and this must be given in a form which will not tax the undeveloped digestive powers. Breast feeding must be aimed at in every case, but only too often this is a counsel of perfection. In spite of every measure to establish lactation, the breast fails to secrete an adequate ration on account of the early date of delivery and the feeble stimulus from the weakly suction apparatus of the baby. Artificial feeding must be resorted to without delay. It is imperative to employ a food whose composition is of a constant standard. The best results will be obtained in carefully estimating the caloric requirements of the delicate infant from day to day. The accurate supply of the calories required demands a food of absolutely standard composition. Excellent results have been reported in these conditions with a diet of separated or half cream dried milk.

The manufacturers of "COW & GATE" milk foods have always been able to reassure the medical profession on the never varying composition of their products. The analyses given below can be depended upon as accurate at all times of the year. This is a great advantage over raw milk, which varies in composition not only from one season to another but from day to day.

Cow & Gate Milk Food

Below are given the percentage compositions and caloric values of the three strengths of "COW & GATE" milk foods:—

	FULL CREAM.	HALF CREAM.	SEPARATED.
Moisture	2.5%	2.5%	3.0%
Fat	27.3%	15.5%	0.8%
Proteins	26.6%	20 0%	35.5%
Lactose	37.6%	57.5%	52.8%
Mineral Matter	6.0%	4.5%	7.9%
	100.0%	100 0%	100.0%
Calorific value per ounce	147	129	104

The manufacturers will gladly supply samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

NINETY-SEVENTH ANNUAL MEETING, MANCHESTER, 1929.

President's Address

ON

THE DEBT OF MODERN SURGERY TO THE ANCILLARY SCIENCES.

BY

ARTHUR HENRY BURGESS, D.L., M.B., CH.B., M.Sc., F.R.C.S.,

PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF MANCHESTER; HONORARY SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

[BEFORE commencing his address the President welcomed the British Medical Association to Manchester and Salford, and expressed his thanks for the great honour of his election to its presidential chair and for the invaluable assistance of medical and lay friends in the preparations for the meeting; he referred to the changes in the personnel of the local profession and of the cities' hospital arrangements since the Association's fourth visit to Manchester in 1902, and mentioned the work during the great war of Manchester's Territorial Hospital—the 2nd Western General.]

In no sphere of the world's activities has a single discovery constituted a sharper dividing line between two stages of its history than in the division of surgery into two periods—pre- and post-Listerian—by Lister's epoch-making discovery of the antiseptic treatment of wounds. Prior to 1865, the year of its first application, the surgical wards of our hospitals, infested as they were by erysipelas, pyaemia, and hospital gangrene, had come to be looked upon as veritable death traps, and a greater measure of success often attended a surgical operation performed in the simple environment of the poorest home than a similar one under the best conditions afforded by the hospitals of that date. The introduction of anaesthesia—surely one of the most merciful events in the history of mankind—had, nevertheless, unwittingly served but to augment the death rate of operative surgery. By abolishing the element of pain therewith associated it had increased the frequency with which surgical operations were performed in theatres and wards where septic infection was the rule, almost without exception, and where suppuration was still regarded as the normal process of wound healing.

Lister has changed all this, but the full extent of that change is very difficult to realize by those of us who, practising surgery sixty years later, and having, therefore, of necessity, had no personal experience of the conditions under which surgeons of the fifties and sixties of the last century had to work, accept the priceless benefits of this radical change almost as a matter of course, and often with very imperfect appreciation of the evolutionary developments that have rendered possible the brilliant surgical work that is being carried on all over the civilized world to-day. As skilled surgical craftsmen, and in their knowledge of anatomy and of the gross manifestations of disease, the older surgeons were in no sense inferior, and yet the ever-present spectre of septic infection rendered each surgical effort a truly perilous adventure, keeping the surgeon in a state of constant anxiety until the wound was safely healed—an anxiety no less disturbing in that, the cause of the infection being unknown, no care or foresight could avail to prevent it.

Commonplace, though none the less true, has now become the statement that Lister's work has revolutionized surgical practice: it has for all time freed surgical operations from the dreaded risks of their most dangerous complication—septic infection—thereby not only vastly increasing their safety, but enormously diminishing the extent of pain and suffering formerly connected therewith. When we consider the incalculable number of lives already saved, the immeasurable amount of suffering already prevented, and the continuation of these benefits throughout the ages yet to come in which surgery will continue to be practised, we must admit that the description given of Lister as the greatest human benefactor the world has yet known is in no sense an exaggeration.

In the numerous Listerian centenary celebrations held two years ago throughout the civilized world the tale of his great discovery has been repeatedly unfolded—how that, like most epoch-making discoveries, it was at first received with incredulity and opposition, against which advancement was slow and laborious. To Edward Lund belongs the credit of introducing Lister's work to Manchester and of establishing antiseptic treatment at the Royal Infirmary. Refused at first by the Infirmary authorities of that day the provision of the requisite antiseptic dressings, Lund for a long while supplied these for his Infirmary patients at his own expense, and mostly prepared them with his own hands. His enthusiasm for Listerian principles and his success in their application steadily wore down all opposition, and antiseptic measures became gradually adopted by his surgical colleagues.

My personal acquaintance with surgery at the Manchester Royal Infirmary dates from 1893, when the transition from antiseptic to so-called "aseptic" methods was just commencing. The carbolic spray had then been given up, yet all operation wounds were still flushed with a strong solution of either carbolic acid or mercury perchloride and thoroughly dusted over with iodoform before being sutured, drainage being almost invariably employed. I well recall an occasion, some two years later, when Walter Whitehead, who was certainly one of the most go-ahead surgeons of his day, announced that he would perform an operation for the removal of a cancerous breast without applying any antiseptic to the wound. Nothing was used save boiled water, nor was the wound drained. This, at that date, very unorthodox procedure excited keen interest among the house-surgeons and dressers, and considerable misgivings were freely expressed as to the result. The wound, however, healed with perfect primary union, and with this encouraging experience antiseptics came to be applied less freely to operation wounds—aseptic gradually replaced antiseptic surgery. The basic principle of aseptic surgery is that everything which comes in contact with the wound during the course of an operation must be sterile, so that, no germs having been introduced, the application of antiseptics is not only unnecessary, but is actually harmful to a degree dependent upon the amount of tissue damage they inflict. In some quarters "aseptic" is spoken of as if it were a rival method to "antiseptic" surgery, and as if it represented a great advance upon anything that Lister had taught. Far from any such antagonism, however, aseptic surgery is but the natural complement and logical outcome of Listerian principles, and although everything else used in a modern aseptic operation may be sterilized by heat, yet the surgeon, worship he never so devoutly at the shrine of asepsis, must use antiseptics for the preparation of the skin of his patient and of his own hands.

As a sequel to the increased safety engendered by the practice of Listerism there naturally followed the extension of surgery into anatomical fields hitherto approached only when urgent necessity demanded the repair of grave injury. Concerned at first mainly with the limbs and the more readily accessible parts of the trunk, attacks were soon made upon the great cavities of the body—the cranial and spinal cavities, the abdomen, and the chest. Thus the operative field has been gradually extended until now every part of the body has been brought within the sphere of surgical activity. Even the heart—always prominent in popular imagination—is no exception; its stab wounds have been many times successfully sutured, bullets have been extracted from its walls and even from its cavities, and plastic operations have been performed actually upon its valves, while injection of drugs directly into the heart muscle, and massage of the heart through either an abdominal or a thoracic incision have become part of the routine treatment of cardiac failure during anaesthesia. At the present time prominent surgical attention is being paid to the last remaining surgically unfamiliar system—the sympathetic nervous system—and to the last remaining organ—the suprarenal body.*

Of the advances that have occurred in almost every branch of surgical work during the present century (a period almost coincident with that since the last visit of the British Medical Association to this city) I think it will be generally admitted that the most outstanding is that in the department of abdominal, and especially of acute abdominal, surgery. This is locally illustrated by a comparison of the abdominal surgery of the Manchester Royal Infirmary at the beginning with that at the end of the first quarter of the present century. During this period, of the general surgical operations the proportion of those on the abdomen has risen from 10.97 per cent. to 56.99 per cent., the annual number of operations for acute abdominal conditions from 82 to 1,241, while their total mortality has diminished from 36.5 to 8.1 per cent. A closer analysis shows that the percentage mortality of operations for strangulated hernia—the only frequently performed urgent abdominal operation in 1900—has fallen from 22 to 9.4, for acute intestinal obstruction from 44.4 to 20.8, for perforated gastric or duodenal ulcer from 80 to 11.1, and for acute appendicitis from 64.2 to 5.1. The enormous increase in the number of operations for acute appendicitis constitutes the most prominent feature of this period. Thus in 1900 only 14 operations were performed in the Manchester Royal Infirmary for this condition—all for either appendicular abscess or peritonitis, there being no recorded instance of removal of an acutely inflamed appendix prior to the onset of one of these complications; in 1924 there were 798 operations for acute appendicitis, of which 337 were performed sufficiently early to permit of removal of the appendix without drainage.

Similar progress, though perhaps less dramatic, has been maintained in the surgery of non-urgent abdominal conditions, the annual number of operations for which at the Royal Infirmary has increased from 184 in 1900 to 1,810 in 1924. The increases shown by the four most frequently performed of these operations are—those for quiescent appendicitis from 24 to 407, for radical cure of hernia from 108 to 333, for gastric and duodenal ulcer from 1 to 250, and for gall-stones from 3 to 176.

Time does not permit me to make more than a passing reference to the present-century advances in other departments of surgical work, though specific mention must be made of the wonderful progress in orthopaedic surgery under the stimulating influence of Sir Robert Jones, of the extraordinary achievements during and since the war in plastic and reconstructive surgery, more especially of the face and jaws, prominently associated in this country with the name of Major Gillies, and of the great increase in our knowledge of the surgical treatment of tuberculosis of the lungs and of other intrathoracic diseases.

This progress in surgery—which, I feel strongly, will compare favourably with that attained in any other branch of the arts and sciences—has not, nor could it have been, achieved without the material assistance of the contemporary advances in the allied sciences; it is, indeed, this which constitutes my main thesis to-night. Modern victories are rarely won single-handed, and the greater the number, the more effective the strength and the more vigorous the activities of the allied forces whence assistance is forthcoming, the more confidently may we look forward to a victorious issue. Prior to the time of John Hunter surgery was almost entirely an art—a glorified handicraft, taught and practised quite independently of all other arts and sciences, devoid of any physiological basis for its methods, and essentially empirical in its attempts at progress. Hunter, deeply imbued with the scientific spirit, introduced into surgery the method of careful observation, collection, and collation of facts, and their thorough testing by direct experimental investigation, rather than that of trusting to theories founded on insufficient and unproved evidence. "Don't think—try" was his favourite exhortation. He it was who first gave allies to surgery, urging that surgery should be regarded as a branch of natural science, to be studied in its appropriate relationship to all the other branches, thus bringing it into close association with chemistry, physics, biology, comparative anatomy, physiology, and pathology. Had the microscope been available in Hunter's day he would doubtless have added to these bacteriology.

Every important discovery in the natural sciences since Hunter's time has exerted its influence upon contemporary surgical thought and practice, and overwhelming indeed would be surgery's debt to its allies were it not offset by a corresponding counter-debt for the help rendered to them in return by the great advances that have been made in surgical knowledge.

Though the choice for consideration to-night of a few only of the numerous component factors of this debt of modern surgery to the ancillary sciences must necessarily prove an arbitrary and rather an invidious task, yet I feel that the consensus of surgical opinion will endorse my selection of physics and of physiology as the two sciences to which, in recent times, surgery is most indebted; and further, that of the many useful applications in surgery of the results of researches in physics three have established a special claim upon our attention—x rays, radium, and light therapy.

RADIOLOGY.

The x rays, discovered by Wilhelm von Röntgen of Würzburg in 1895, were early applied to the diagnosis of pathological states in the human being, and thus was founded the science of radiology, whose subsequent brilliant achievements not only constitute one of the most important chapters of progress in medical affairs during the present century, but also open up vistas of still greater possibilities for the future.

The organs and tissues of the body vary in the degree of resistance they offer to the passage of the x rays, and it is upon the relative opacity of an organ to that of the tissues in its immediate vicinity that the possibility of demonstrating its shadow upon the radiographic plate or screen depends. The bones and teeth are very much more opaque than the soft structures, and cast the deepest shadows; the lungs are the most translucent, so that the heart placed between them is relatively opaque, and casts a very definite pulsating shadow. The kidneys are seen only to a very limited degree, since they are surrounded by tissues of approximately the same density as themselves; were they situated in the thorax their visibility would equal that of the heart.

Foreign bodies are displayable in proportion to their density, those of a metallic nature taking the first place. Had we not had available during the great war the assistance of the x rays in the detection and accurate localization of the bullets, shell fragments, and other metallic particles lodged in the tissues of so many of our wounded, war surgery would have had a very much less successful tale to unfold. Calculi are opaque to the x rays proportionately to the amount of lime salts they contain, those of the urinary tract being nowadays displayed with

* Oppel of Leningrad, in *Annals of Surgery*, June, 1928, reports 130 adrenalectomies for Raynaud's disease, and other forms of "hyperadrenalinaemia."

such reliability that operations for the removal of renal and ureteric stones are practically never undertaken unless the presence of the calculus has been previously radiographically demonstrated. In the bladder, it is true, stones are occasionally met with composed of uric acid only and quite translucent ("radiolucent") to the *x* rays; such may easily be overlooked even if of large size, but fortunately we have, in the cystoscope, a certain means of their recognition. Calculi in the salivary and other glands are readily displayed, while, with improving technique, gallstones are being shown in a steadily increasing proportion of cases.

The assistance of the *x* rays in the diagnosis and treatment of fractures and dislocations has proved invaluable, and the advice given recently by the council of the Medical Defence Union in a circular letter to its members, to insist upon radiography in every case of suspected fracture, would appear to be extremely sound from several points of view other than the intended one of defence against a possible legal action for malpraxis. Radiography soon taught us that in a large proportion of what were formerly considered to be merely "sprains" of joints some definite bony injury was present, the overlooking of and consequent failure to apply appropriate treatment to which explains the popular idea that "a sprain is worse than a break." Many incomplete and impacted fractures, and some of those without displacement, cannot be detected by any other means than radiography, and of this the general public is becoming aware. The public is, however, much too prone to estimate the success or failure of treatment of a fractured bone by the extent of the anatomical deformity displayed in the radiogram, rather than by the functional result; to the popular mind the "setting" of a fractured bone seems to imply that the radiographic picture should show the perfect apposition of the broken surface—an ideal which, though frequently most eloquently stressed by counsel for the plaintiff in an action for malpraxis, is, as the medical profession knows only too well, rarely attainable apart from open surgical operation.

X-ray apparatus is now so efficient that the finest details of structure of the bones are easily shown, and the slightest changes therein induced by early disease can be readily detected. Thus the earliest manifestations of tubercle, of rickets, of syphilis, and of new growths as they affect bone are readily recognizable, and such knowledge conduces to earlier and more effective treatment. One of the commonest applications of radiography of the present day is that to the sockets of the teeth, and many a local source of origin of "focal sepsis," otherwise inexplicable, has been thereby disclosed.

At an early stage of radiography its utility was vastly extended by the introduction of substances opaque to the *x* rays into parts of the body otherwise radiolucent, thus rendering them visible. The ramifications of sinuses in the soft parts were demonstrated radiographically by previously injecting them with bismuth paste. The introduction of the bismuth and, later, of the barium meal has been *the* outstanding advance in radiology, and has completely changed many of our former ideas regarding the anatomical position, the form, and the physiological movements of the different parts of the alimentary tract, while it has added in a truly marvellous degree to our knowledge of their pathology. Radiology, to the infinitely greater safety of the patient, has entirely displaced the bougie in the diagnosis of oesophageal obstruction, and yields an accuracy of information as to the exact situation, extent, and nature of the cause of the obstruction previously quite unattainable. It thus differentiates readily between simple cicatricial stricture, malignant stricture, compression of the oesophagus by tumours from without, and the very imperfectly understood muscular obstruction at its lower end, to which the term "cardiospasm" is applied. The presence, situation, size, and shape of pharyngeal and oesophageal diverticula are demonstrated with certainty by means of the opaque meal, which has also taught us that diverticula of the alimentary canal, though most frequently met with in the pelvic colon, may occur also in the rest of the large intestine, in the appendix, the small intestine, the duodenum, and even in the stomach. The recognition of gastric and duodenal ulcers, of their complications, such as hour-glass contraction and pyloric stenosis; of gastric cancer, more particularly in its earlier stages; of obstructions of the intestines, especially that of carcinoma of the colon, by means of the opaque enema, either alone or in combination with the opaque meal; of displacements of the viscera such as are observed in diaphragmatic hernia or in visceroptosis, and the demonstration by Graham's method of the outline of the gall-bladder some ten to twelve hours after the administration of tetraiodo-phenolphthalein, owing to the power of this viscus to concentrate the bile, in which the drug is excreted, to such a degree as to prove opaque to the *x* rays—all these constitute veritable triumphs of radiology, and have enormously facilitated the diagnosis of abdominal conditions.

Much the same may be said of the application of the opaque ureteral bougie and of the introduction of opaque media into some part of the genito-urinary tract during radiography—pyelography, ureterography, cystography, or urethrography, according to the portion of the tract concerned. Of these, pyelography has been most employed, and has disclosed alterations in the size, shape, and position of the renal pelvis, calyces, and ureters which have proved of the highest possible value in the diagnosis of renal pathological states.

The introduction into the trachea of the opaque medium lipiodol—a combination of 40 per cent. iodine with oil of poppy seeds—renders the bronchi and their ramifications visible upon a radiogram taken very shortly afterwards, and has been found useful in determining the relation of a foreign body in the lung to the nearest accessible bronchus, in demonstrating the outlines of lung abscesses, the presence and extent of bronchiectasis, the existence of a broncho-pleural fistula, and the extent of malignant growths involving the bronchi. Lipiodol was originally recommended by Sicard of Paris in 1921 for the localization of the site of blockage of the subarachnoid space by spinal cord tumours. Introduced into the upper part of this space, as by injection into the cisterna magna, the medium falls by gravity to the level of the upper limit of the obstruction, and can there be radiographically shown. By injecting into the lumbar sac an "ascending" mixture of lipiodol and olive oil, of lighter specific gravity than the cerebro-spinal fluid, the lower extent of the subarachnoid block can be defined. The method is not altogether devoid of danger, and lipiodol, once introduced, appears to remain unabsorbed for a long period, even for years. The injection of lipiodol into the uterine cavity has been used to indicate its size and shape, and any encroachment upon it, as by a growth, while the failure of the medium to pass along one or both Fallopian tubes has been utilized in the diagnosis of their obstruction in cases of sterility.

Another method of altering the relative densities to *x* rays of adjacent soft structures, and thus rendering their outlines visible, is the introduction of a gaseous medium—air, oxygen, or carbon dioxide—as into the perirenal tissues, thereby allowing the outline of the renal shadow to be readily discerned; or into the peritoneal cavity, when the liver, spleen, and kidneys are rendered visible. The withdrawal by puncture through a drill hole in the skull of a small amount of fluid from one of the lateral ventricles of the brain and its replacement by air or oxygen has allowed the outlines of the ventricles to be rendered visible upon the radiographic plate; their increased size in internal hydrocephalus can thus be readily demonstrated, whilst the position relative to the ventricle of an otherwise obscure cerebral tumour can often be accurately ascertained.

The growing importance of radiology is evidenced by the steadily increasing proportion of patients who pass through the *x*-ray department of our hospitals either for diagnosis or treatment. At the Manchester Royal Infirmary this proportion has gradually risen from 1 in 100 in 1908 to 1 in 24 in 1912, 1 in 11 in 1917, and 1 in 5 in 1928.

RADIUM.

Radium was discovered in 1898 by Professor and Madame Curie in a deposit of pitchblende from Jonchimstal in Bohemia, and was at first a monopoly of the Austrian Government. This monopoly was transferred to the American Government in 1913 owing to the discovery in Colorado and Utah of carnotite—a mineral which, although

the proportion of radium it contained was as small as one gram in 400 tons, nevertheless proved profitable to work owing to the ease with which the radium could be extracted. The finding of some very rich lodes of pitchblende in the Belgian Congo in 1921 has now placed the monopoly in the hands of a Belgian syndicate, who, in their factory at Oolen, at present supply most of the world's demand. It requires from thirty to forty tons of ore to yield one gram of radium, and its extraction necessitates spacious premises, much labour, and many highly skilled operatives, all these factors being reflected in the present market price of about £12,000 per gram. This monopoly seems likely to persist for some time, and only the discovery of a new source of really rich deposit can ameliorate the present situation.

Radium emits rays of three varieties—alpha, beta, and gamma—the last, similar to the Roentgen rays, and of high penetrative power, being those mainly used in deep treatment. Upon both animal and vegetable life radium has a decidedly detrimental effect, which is not, however, exercised equally upon all tissue cells, and even upon normal tissues radium has a decidedly selective action. Thus the cells of glandular structures, especially those of the ovary and testis, are much more susceptible than those of fibrous tissue, while muscle, cartilage, and nerve cells are the least sensitive. Actively dividing cells are the most vulnerable, and the cells of malignant growths, in which activity of cell division is a prominent feature, are more readily affected by radium than the other cells of the body. Upon this selective action the therapeutic value of radium in cancer depends, and our problem is to determine the exact dose that will exert the maximal destructive effect upon the cells of the malignant growth with the minimal upon those of the other tissues. There is a minimal dose below which no destructive action occurs, and many believe that these weak irradiations can stimulate the growth of tumour cells, and even stir into activity cells actually quiescent. The total dosage of radium, calculated in milligram-hours, can be applied either as a large amount of radium acting for a short time, or a small amount acting for a long time, and opinion is not yet decided upon the optimal dosage for each type of growth. On the one hand, by prolonging the duration of exposure, a greater number of cells will be adversely influenced during the vulnerable stage of active cell division; on the other hand, it has been shown experimentally that repeated sublethal doses may actually increase the resistance of the tumour cell to radium, and radiation treatment should, therefore, be concluded within a reasonably short time, and not indefinitely repeated.

As a therapeutic agent radium has been found of considerable value in non-malignant conditions—such as naevus, keloid, lupus and other skin diseases, exophthalmic goitre, and benign tumours—but it is in the treatment of malignant disease (including rodent ulcer) that its chief interest to us lies. Restricted at first entirely to cases too advanced for radical operative treatment, its scope has within the last few years been extended, either alone or in combination with surgery, to the treatment of operable cases. There has arisen a special branch of surgical technique—"the surgery of access"—concerned with the planning of operative procedures for the appropriate exposure of deeply seated malignant growths in order that radium tubes may be placed in correct relation thereto—as when a rectal carcinoma is exposed by removal of the coccyx and lower portion of the sacrum, an oesophageal carcinoma through the posterior mediastinum after rib resection or across the pleural cavity by lateral thoracotomy, or an intralaryngeal growth through a "window" cut in the thyroid cartilage. Modern methods of radium application have met with such considerable success in cancers of the skin, of the cervix uteri, of the mouth and tongue, and of the larynx, that there is an increasing tendency in these cases to prefer radium to operative treatment, at any rate so far as the primary growth is concerned. The comparatively slight disturbance of radium tube insertion, or of radium bomb treatment, their lesser risks, and the absence of that mutilation necessarily associated with a radical surgical operation, and which, as in the case of the tongue, may prove a considerable and permanent disadvantage, are factors favourable to radium, and should tend to overcome the natural reluctance of the average patient to submit to early treatment. It is, however, upon the end-results that the question must be ultimately decided, and these are not yet sufficiently known in the case of radium for a conclusive judgement, although some promising series of five-year statistics have been reported. In many cases the best results are obtained by a combination of radium treatment with surgery, as when the radical operation for cancer of the breast is associated with the implantation of radium tubes or needles into the supraclavicular and anterior mediastinal regions. At the present moment expert opinion seems to favour reversion to the external application of radium, either alone or in combination with radium tube insertion and very short wave-length x-ray irradiation. There are, however, two most important changes from the surface applications as originally practised: (1) the much larger quantities of radium used—up to 4 grams—and (2) the much greater distance from the skin—as much as 16 cm.—at which it is applied, thereby ensuring a more uniform dosage to all parts of the area irradiated, with lessened risk of cutaneous damage. This "bomb" or "cannon" treatment—as at present carried out in Paris, Brussels, Stockholm, and on a smaller scale at the Westminster Hospital, London—is considered by many likely to prove the method of choice in radium therapy, and it certainly deserves to be tested very thoroughly, should a sufficiency of radium be forthcoming. The still very high cost of radium in spite of the removal of the one-third *ad valorem* Government duty, and its restricted supply, are matters requiring urgent attention, and every means must be taken not only to increase its production, but also to ensure that the most efficient and most economical use is made of such supply as is already available, having regard to the absolute necessity, in this connexion, of maintaining an intimate association between treatment and research. The technique of radium therapy is highly specialized, and such work should be centralized, and restricted to the expert staffs of special institutions established in a few of the largest cities of a country. Until the supply of radium becomes less inadequate to cope with the increasing demand it may be advisable to arrange for a "night" as well as a "day" staff of workers at these institutions in order to minimize the number of hours ("radium-hours") during which any of the radium is unemployed in treatment.

ACTINOTHERAPY.

Heliotherapy—treatment by sunlight—is probably as old as human history. Hippocrates (460 to 370 B.C.) refers to the effect of sunlight in promoting health, and recommends sufferers from various ailments to walk about naked in the sun as much as possible—a simple remedy, which seems, however, to have been overlooked for many subsequent centuries.

At the end of the last century a considerable proportion of the beds in the hospital wards of our large cities was occupied with cases of tuberculous disease of the bones, joints, and spine, and other forms of "surgical" tuberculosis, for which operations, often of a very extensive and mutilating nature, and frequently requiring repetition, were considered the only chance of a cure. How frequently they failed, and, even when successful in saving life, the unsightly deformities and fearful defects of function that resulted, are some of the unpleasant memories of those of us who practised at that time. No more beneficent change has occurred in any department of treatment than in that of surgical tuberculosis during the past quarter of a century.

Thanks to the pioneer work of Bernhard and Rollier in Switzerland, and of Sir Henry Gauvain and Sir Robert Jones in this country, these mutilating surgical operations are things of the past. Surgical tuberculosis is nowadays treated by a general exposure of the body to sunlight in the open air in summer, and to artificial sunlight in the winter or whenever natural sunlight is not available. This should be combined with local treatment so designed as to ensure complete immobilization of any active focus, the removal of any pressure or weight-bearing, the correction, so far as is possible, of any existing deformity, and the antiseptic care of any discharging sinuses. Active surgery is limited almost

entirely to the evacuation of any cold abscesses that may develop, although in tuberculous spinal disease operations (Albee's, Hibb's) are occasionally performed, not as a direct attack upon the affected tissues, but to ensure better immobilization of the morbid focus in the vertebral bodies by producing ankylosis of the spinous processes of the diseased vertebrae and of those immediately above and below. Under this modern plan of campaign not only is victory assured in a much greater proportion of cases, but the bronzed and robust-looking bodies of the patients under sunlight treatment contrast pleasurably with the waxen faces and wasted limbs of the old days, while the local focus of disease heals with the minimum of deformity and the maximum preservation of function.

Treatment by ultra-violet radiation (actinotherapy) is now being extended to rickets and other general diseases, to most forms of skin disease, and to many disorders of the circulatory, respiratory, alimentary, nervous, and genito-urinary systems, as well as to those of the special senses. It has, in fact, assumed the dimensions of a "boom" treatment, and "sunray" centres are being established all over the country, not only as private ventures, often controlled by laymen only, but also at the municipal bathing establishments of many of our cities and towns, while there are sunbaths in many factories and at "pitheads" in several of our coal-mining districts.

The ultra-violet rays are, however, far from being innocuous, and their correct dosage is a matter of great importance and of careful individualization, since what is a safe dose for one may be dangerous to another. Over-exposure to their influence produces sleeplessness, restlessness, loss of weight, lassitude, and even sickness, while severe burns and serious forms of dermatitis may result in sensitive persons. Moreover, some ailments are adversely influenced by ultra-violet ray treatment—notably chronic nephritis, arterio-sclerosis, and quiescent tuberculosis, the last of which may easily be stirred into renewed activity. It is therefore in the public interest that the prescription of ultra-violet rays be restricted to the medical profession, and that their application be undertaken only by those who have received a proper course of training for this special work.

In view of the risks to the public involved in the use of electricity and radiation as methods of treatment by untrained and unqualified persons, the Representative Body of the British Medical Association, at the last Annual Meeting (July, 1928), expressed the opinion that suitable courses of training should be organized under medical direction for persons wishing to administer this form of treatment; that persons who have satisfactorily followed such a course should be entitled to have their names entered on an approved roll; that they should undertake to treat only patients sent to them by medical men, and that medical men should refer their patients only to those persons whose names are on the approved roll. Along these lines the Society of Apothecaries of London, acting in concert with the British Medical Association, has recently agreed to set up a standard to which persons practising physio-therapeutic treatment should attain, to institute a diploma, and to establish a register of those found qualified to serve as "biophysical assistants," such registration to entitle the appendage of the letters "B.P.A." to their names. The unqualified, unregistered chemist, dentist, and midwife are forbidden by law, and it seems only logical that the unqualified electrotherapist, who handles therapeutic measures equally potential of danger, should be placed under similar legal control.

PHYSIOLOGY.

Physiology has often been referred to in the past as the handmaiden of medicine, but such a description very inadequately represents its present status as a proud and independent branch of true science—the science of life itself. Rather must it be described as the essential foundation of modern medicine and surgery, as the means by which many of our former purely empirical methods of treatment have been placed upon a rational basis, and as the main factor by which the practice of medicine and surgery is daily becoming proportionately more of a science and less of an art. That the element of art must continue permanently to play a considerable part in surgery is self-evident when we remember how largely handicraft enters into its daily routine, but the merely artistic aspect of surgery has now, we may fairly claim, been brought to so high a degree of perfection that it is not so much upon outstanding advancements in surgical artistry that we must rely for future progress as upon a more thorough understanding of the physiological principles involved in our work, and their application to what is, after all, the great aim of surgery—the restoration of deranged function to the normal. The greater comprehension the surgeon obtains of what constitutes normal function the better equipped is he to achieve this aim, and to improve his methods by means which were not possible in the days when physiology was less advanced. The surgeon and the physiologist must tread the path of progress hand-in-hand, to the great advantage of each, since the debt between them is essentially a mutual one. For the success of his experiments upon animals the physiologist has to depend largely upon the methods of modern aseptic surgery, and has, therefore, a very vital interest in any improvements in surgical technique that may from time to time accrue. Moreover, though it is true that many discoveries made by physiologists which have found valuable practical application in medicine and surgery have originated purely in the search after truth and without any thought of their possible clinical utility, yet, on the other hand, there are many instances where clinical observation has been the starting-point of physiological researches which have ultimately proved of the greatest benefit in the treatment of human disease. One of the most impressive illustrations of this is yielded by the development of our knowledge of the localization of function in the cortex of the brain.

Prior to 1861 physiologists taught us that the brain acted as a whole, without any allotment of specific function to localized areas within it, but with all its parts working equally together. In that year Broca demonstrated to the Anthropological Society of Paris the brain of a man who had lost the power of speech for forty-one years, and showed that the only pathological change was softening of the third left frontal convolution. From this and other observations Broca deduced that this area was the seat of the faculty of articulate speech, and he further made the revolutionary suggestion that other areas of the brain might similarly be associated with special localization of function. In 1869 that great clinical observer Hughlings Jackson, from a study of cases of fits, and of hemiplegia, in which he carefully correlated the clinical manifestations with the necropsy findings, advanced the opinion that the cerebral cortex could be divided up into separate areas with distinctive function in regard to voluntary movement. In 1870 Fritsch and Hitzig applied the methods of experimental physiology, and by means of a galvanic current electrically stimulated the exposed cerebral cortex in dogs; they found that co-ordinated movements of certain muscles on the opposite side of the body invariably followed upon stimulation of certain definite areas of the cortex. In 1873 David Ferrier repeated and extended these experiments to the monkey, and utilized the faradic in preference to the galvanic current. He proved conclusively that certain portions of the cortex are definitely associated with specific motor and sensory functions, and his results were subsequently confirmed and extended by Horsley, Schafer, Beevor, Sherrington, and others who made similar experiments in the higher apes and in man. The way was thus paved for the application of these experimentally obtained results to man, and in 1876 Macewen (the late Sir William Macewen) of Glasgow correctly diagnosed an abscess in the immediate vicinity of Broca's lobe, the result of an injury to the skull. Unfortunately consent to operation could not be obtained, but after death the friends allowed the operation to be performed just as had been intended during life, when the finding of an abscess the size of a pigeon's egg in the white matter of the bases of the second and third frontal convolutions showed how accurate had been the diagnosis. In 1879 Macewen successfully operated upon two cases—one of abscess and one of tumour; in 1884 Godlee reported an operation for cerebral tumour; in 1886 Horsley recorded three cases of cerebral surgery; and in 1888 Macewen, in his address to the British Medical Association in Glasgow, recorded 21 cerebral operations with 18 recoveries, the three fatal cases all being *in extremis* when operated upon.

Since that time the continued experimental investigations by physiologists, the carefully recorded clinical observations of physicians, and their correlation with the results either of necropsy findings or of the operative disclosures of their surgical colleagues, have each played their part in the acquisition of the infinitely fuller, though even yet far from complete, knowledge of the localization of cerebral function of the present day—a knowledge which constitutes the essential basis of the great advances that have occurred during the present generation in the realm of cerebral and intracranial surgery.

Age[illegible] e functions of the thyroid gland
comm[illegible] bservations of Caleb Parry (1786),
Grov[illegible] (1840) on the condition we now
desig[illegible] and those of Curling (1850), Sir
Willi[illegible] (1877) on the opposite condition
of[illegible] which Ord applied the term

"myxoedema." Schiff of Geneva had shown in 1856 that removal of the thyroid in dogs led to a fatal result; in 1882 A. and J. Reverdin of Geneva produced myxoedema in animals by total or partial thyroidectomy, and in 1883 Kocher of Bern reported that of 100 cases in which he had removed large goitrous tumours from human beings 30 developed the condition he described as "cachexia strumipriva," which he attributed to injuries of structures in the neck rather than to the loss of the thyroid. In the same year Sir Felix Semon suggested, at a meeting of the Clinical Society of London, that myxoedema, cachexia strumipriva, and cretinism were identical, and were due to loss of function of the thyroid gland. The Clinical Society of London thereupon appointed a commission to investigate this question, and selected Victor Horsley to undertake the experimental part of the work: he produced cachexia strumipriva in monkeys and other animals by removing the thyroid gland. In 1884 Schiff, repeating his previous experiments upon dogs, showed that death after thyroidectomy could be averted by transplanting the gland under the skin or into the peritoneal cavity, and von Eiselsberg proved the same to be true of the cat. In 1890 Horsley independently suggested thyroid grafting to arrest myxoedema in man; this suggestion was acted upon by several surgeons, especially Bettencourt and Serrano, who attributed the improvement following immediately upon operation to absorption of the juice of the transplanted gland. Thereupon Murray, in 1891, suggested that the regular administration of the thyroid secretion in the form of an extract of the gland would remove the symptoms of myxoedema; he prepared a glycerin extract of a sheep's thyroid and injected it hypodermically at intervals into a patient with myxoedema, all the symptoms of which rapidly disappeared. In the following year Howitz of Copenhagen, and Hector Mackenzie and Fox in this country, found that a similar good result could be obtained by oral administration of thyroid extract or of the raw fresh gland itself, and thus was inaugurated the wonderfully successful thyroid therapy of the present day.

The progress of physiology during the present century has been characterized by many new methods of study, by the greater attention devoted to human physiology, and by the enormous strides made in the physiology of nutrition. If we look back to the beginning of this century and compare the state of physiological knowledge then with that of the present day it is wonderful to contemplate the discoveries that have been made. The use of x rays for the examination of the function of the stomach and small intestines, developed first of all by Cannon for physiological purposes, had only just begun to be applied to the diagnosis of alimentary diseases. The role of proteins in nutrition was imperfectly understood and their chemical constitution was only a conjecture. Vitamins had not been heard of. Insulin was still a hypothetical substance. None of the active principles of the ductless glands had been synthesized and their mode of action was very incompletely known. Micro-methods for the biochemical examination of the blood and other body fluids were practically unknown. The buffering mechanisms of the blood were not dreamt of, and the close interplay between normal physiological functions such as secretion and respiration, and their part in the regulation of body neutrality, was not known. The relation of the capillary circulation to the production of shock is also a relatively recent discovery.

All these advances in knowledge, and many others that might be mentioned, have had their influence on surgery—directly, because they have improved methods of diagnosis and treatment, and indirectly on account of their influence on the attitude of the surgeon to his subject. It is impossible to deal in detail with each particular advancement which surgery owes to physiology, but a few examples may be mentioned.

Rickets.

This disease, responsible for a large number of the deformities with which surgeons have been called upon to deal, may be expected to disappear within the next decade, as a result of the discoveries which have been made on the influence of vitamins, and especially vitamin D, on nutrition. It is a matter of congratulation that the pioneer work of Hopkins on the discovery of vitamins, and of Mellanby on the dietetic factors which influence the development of rickets in dogs, was done in this country. In 1915 Mellanby showed that rickets was a "deficiency disease" due to absence from the diet of some unknown factor which controls the calcification of bone and the development of the teeth, and he thus foreshadowed the discovery of a fourth vitamin now known as "vitamin D"—the antirachitic vitamin. It was shown that rickets experimentally produced in animals could be readily cured by administering cod-liver oil, and the same was known to be true of rickets in children. This knowledge was successfully utilized on a large scale in Vienna in 1919 for the treatment of children afflicted with rickets as a result of an insufficiency of fats in their diet during the great war, when, in the Mid-European countries, all available fats were deflected to the production of high explosives. It was there observed that rickets was much more easily cured in summer than in winter, and that exposure to the summer sunlight alone, even without the administration of cod-liver oil, could arrest the disease. Later the discovery was made that exposure to the ultra-violet rays from a carbon arc or a quartz mercury vapour lamp had the same beneficial effect as sunlight or as cod-liver oil; while, still later, irradiation of the body of the child or animal was proved to be unnecessary provided that the food be exposed to the ultra-violet rays prior to administration. Tests applied to the different constituents of the food indicated that only the fatty portion could be activated by ultra-violet irradiation, and by further elimination the essential factor concerned was finally shown to be "ergosterol"—one of the group of sterols usually associated in small amount in the human body with cholesterol, and found plentifully in yeasts and in the fungus ergot of rye, from which it was first isolated. On exposure to the ultra-violet rays ergosterol changes from a white crystalline substance to a pale yellow resinous material, which is the most potent in vitamin D content of any known body. It is estimated that 5 milligrams of this substance is the equivalent in antirachitic power of one litre of cod-liver oil, and the daily dose needed to prevent rickets is only a small fraction of a milligram. Upon the presence of ergosterol in the natural fats of the skin, and the production of vitamin D by the action thereon of the ultra-violet rays, depends the curative power of sunlight on rickets.

Irradiated ergosterol is now produced on a commercial scale by many of the large drug firms, under such names as "radiostol," "vigantol," etc., and by its substitution for cod-liver oil the preventive and curative action of the latter upon rickets can be obtained without the disadvantage of its taste, or of its tendency to upset digestion. This direct production of vitamin D is certainly the most important advance yet made in the chemistry of the vitamins, and has not only paved the way to a rational therapy of rickets, but, better still, has pointed out methods of prevention that should lead to its disappearance. Mild degrees of rickets are, unfortunately, still very prevalent, and in a recent report Sir George Newman states that as a result of the examination of nearly 1,000 children of 3 years of age in various parts of the country some manifestation of rickets was discovered in as high a percentage as 48.7. The time required for cure by the various methods of treating rickets is a question of some practical importance. At Alder Hey Hospital, Liverpool, Dr. Aidin (*Lancet*, February 4th, 1928) found that in severe cases treatment by antirachitic diet together with cod-liver oil effected a cure, as shown by radiological examination of the bones, in approximately fifteen weeks; additional treatment by exposure to the tungsten-cored carbon arc lamp shortened this period to nine weeks; while the further addition of irradiated cholesterol internally and the substitution of the quartz mercury vapour lamp for the tungsten carbon arc brought about a radiological cure in approximately five weeks. Not only has this new treatment of rickets—the administration of concentrated vitamin D—an apparent advantage in point of time, but its great convenience, its exactness of dosage, and its economy are all in its favour. Before its adoption on an extensive scale, however, much requires to be known as to the stability of the new preparations, their keeping properties under various conditions, the exact dosage required for the cure of human rickets, and the possible dangers of excessive dosage.

Blood Transfusion.

This, one of the most useful of our emergency surgical therapeutic measures, although first performed upon animals by Lower so long ago as 1666, and upon a youth of 15 years by Denys of Paris in 1667, was very little

practised until the present century. Thus was largely owing to the uncertainty of the outcome, the blood of one man not being always compatible with that of another, but sometimes reacting so that the corpuscles of the donor's blood are agglutinated by the serum of the recipient, and more or less rapidly destroyed; not only does the recipient then fail to receive any benefit from the transfusion, but injurious consequences may ensue varying from slight discomfort to sudden death. The physiological researches of Jansky in 1907 and of Moss in 1910 (in America) into the interaction of a large number of specimens of human blood led to the establishment of the four now well-known blood groups. The blood of individuals belonging to the same group may safely be transferred from one to another, and even if of different groups may still prove compatible under certain conditions of admixture now fully investigated. Simple means have been discovered of determining the group to which a person belongs, and consequently this valuable surgical procedure has been reintroduced on a sound physiological basis, while an increased knowledge of the phenomena of blood congulation has evolved a relatively simple technique—the sodium citrate method—which has largely replaced the older one in which the blood vessels of the donor and recipient were directly connected. In the war it was not until the advent of the U.S.A. army medical officers in 1917 that blood transfusion was utilized on any large scale, but thereafter it proved invaluable as a means of combating haemorrhage and shock, both of which factors were usually associated with the extensive wounds of warfare. In the surgery of civil life blood transfusion is destined to play a steadily increasing part in the treatment of acute anaemia, whether due to haemorrhage alone, as in severe haematemesis from gastric or duodenal ulcer, or to secondary haemorrhage from an amputation stump: or whether associated with shock, as in severe industrial railway and motor-car accidents, and after serious surgical operations. In such emergencies there can be no question as to its immediate life-saving value. Transfusion has also proved of great benefit in the more slowly developing anaemia of repeated small haemorrhages, such as occur in ulcers and malignant growths of the stomach and colon, and has frequently enabled a radical surgical operation, otherwise quite impossible, to be safely undertaken. In jaundice, purpura, haemophilia, and other haemorrhagic diseases, transfusion, in addition to replacing the blood actually lost, has a beneficial effect upon the tendency to haemorrhage; in pernicious anaemia repeated transfusions, though not a cure for the disease, may prolong life for months or even years; in pyogenic infections transfusions of blood from a donor, who himself is first actively immunized ("immuno-transfusion"), has met with some success and is at present on its trial; whilst in other toxaemias and in other directions blood transfusion is being increasingly utilized.

Insulin.

Although the isolation of insulin and its preparation in a suitable form, standardized for therapeutic use, is a triumph of physiology which finds its greatest use to the physician in the treatment of diabetes, yet it has not been without its value to the surgeon. Diabetic patients require surgical attention proportionately much more frequently than non-diabetics, or than sufferers from other chronic diseases. Thus Fitz found that 14 per cent. of 386 diabetics consecutively treated at the Massachusetts General Hospital required surgical intervention, chiefly on account of the frequent occurrence of carbuncle and of gangrene. Prior to the introduction of insulin a high mortality attended surgical operations in diabetes, mainly owing to slow healing of the tissues, to their increased liability to infection, and to the frequent development of post-operative coma; insulin administration, together with precision in diet, has so completely transformed the surgical outlook that, as reported from the Mayo Clinic in 1926, no patient is now refused any necessary operation because of diabetes, and the mortality of operations upon diabetics has been reduced to that in cases without this complication. It seems likely that in the future, with a better knowledge of the part played by insulin in carbohydrate metabolism, it may find other uses. Its value in furthering the deposition of glycogen has already been applied to the improvement of the functional activity of the liver, and in cases of inanition which have to be operated upon it may be of value in rapidly inducing a better nutritive condition of body tissues; while the combination of glucose intravenously with insulin subcutaneously has proved of considerable value in the treatment of shock, creating an immediate supply of energy from the rapid oxidation of the glucose by insulin.

Assessment of Renal Function.

It is principally to the painstaking and persevering work of the American biochemist Folin that we owe the modern micro methods of blood analysis whereby, using only a few cubic centimetres of blood, all the important constituents can be accurately determined. These methods have been particularly helpful in cases where prostatectomy is contemplated and where it is essential to know to what extent the excretory functions of the kidneys have been already adversely affected by back-pressure from the prostatic obstruction, as indicated by the abnormal retention in the blood of urea, uric acid, creatinin, and other waste products to an extent varying directly with the degree of renal derangement. It cannot, in fact, be too strongly stressed that the operative risks of prostatectomy are concerned infinitely more with the condition of the kidneys than of the prostate, and that by delaying the major operation until the renal functions have been improved by the relief from "back-pressure" afforded by adequate preliminary drainage of the bladder—either by the indwelling catheter or by suprapubic cystostomy—the dangers attending the removal of the prostate can be very materially diminished. Biochemists, by means of their tests of renal functional capacity, have enabled surgeons to estimate the power of the kidneys to withstand surgical intervention with a degree of accuracy that is truly remarkable. Would that the same could be said of the liver, and that we could "size up" the functional state of that organ as simply and as correctly as we can that of the kidneys. So manifold and varied, however, are the functions of the liver, and so diverse the directions in which deranged hepatic function may become clinically manifest, that any reliable estimation thereof must necessarily involve more extensive and more complicated procedures than in the case of the kidneys.

Of other methods of applied physiology to which the surgeon is indebted, mention may be made of the use of fractional gastric analysis for investigation of the activity, both digestive and motor, of the stomach; the duodenal tube for the collection and examination of bile; estimation of the basal metabolism as a guide to over- and under-activity of the thyroid and pituitary glands, and to the nature of the operative procedures to be undertaken in connexion therewith; determination of the carbon dioxide combining power of the blood and its relation to the diagnosis of those conditions of acidosis and alkalosis that occasionally complicate surgical procedures; and the examination of the red blood corpuscles for "fragility" in cases of splenic enlargement, as in haemolytic jaundice.

In the past a large proportion of the discoveries of physiology has been the outcome of experiments upon animals, conducted in physiological laboratories, while the wide field for the investigation of its problems offered by the hospital wards and operating theatres has been comparatively little utilized. For the elucidation of many points man himself possesses several advantages over the lower animals as a subject of investigation, and a more active encouragement of clinical research in human physiology is one of the prominent needs of to-day. In Manchester the University professor of physiology has been placed along with his colleagues in anatomy, physics, and pharmacology, upon the consulting staff of the Royal Infirmary, so that the closest possible connexion is maintained between these ancillary sciences and the clinical aspects of medicine and surgery.

Pregnant with promise, too, is the recent extension of physiological research to the whole field of human activity. Laboratory investigations have taught us much of the

physical and chemical workings of the individual systems of the human body, and have supplied us with various measures by which these can be tested. But of the workings of the human machine as a whole under the varying conditions and stresses of industrial and other forms of activity comparatively little was known. Early in the war it was recognized that the methods of medical examination of recruits then in vogue were far from satisfactory, and their inefficiency was frequently shown up on the parade ground and in the training camps. Especially was this so in the case of individuals in the Royal Air Force, where it was soon recognized that perfectly "sound" men, in the usually accepted medical sense, might nevertheless be quite unfitted to control an aeroplane. New and more delicate tests were required of the functional activity of the various systems, especially the visual, circulatory, and nervous systems, and of their quickness of response to the constantly changing conditions met with in flying. The medical officers of the Royal Air Force have shown most praiseworthy ingenuity in devising methods for the more efficient testing of the body functions, and have given a great impetus to the study of the healthy human machine at work under conditions hitherto unknown. In the field of industry it is becoming more generally recognized that the test of health is the capacity to perform effective work, and researches are constantly being made into the effects of environmental factors—for example, fatigue, monotony, noise, high illumination—upon the productive efficiency of the industrial worker. It has been shown that the distribution of industrial accidents amongst workers exposed to similar conditions of risk is not a mere matter of chance, but that each has an individual proneness to accident which can be fairly exactly estimated by testing the rapidity and accuracy with which he reacts to certain visual, auditory, and tactile stimuli. Though much still remains to be accomplished, the valuable information thus acquired has already brought about vast improvements in working conditions in many of our industries, and in the standard of health and the productive capacity of those employed therein.

Of modern surgery's debt to the other ancillary sciences that to bacteriology is assuredly the most fundamental, since it was Pasteur's discovery that fermentation and putrefaction were caused by minute living organisms and were, therefore, vital and not merely chemical processes, as hitherto believed, that led Lister to his great conception of the antiseptic treatment of that putrefaction then found in almost all wounds—a conception which constitutes, as we have seen, the very starting point of modern surgery. Time permits me merely to mention other advances in bacteriology: the detection of the causative germs of almost all the infective diseases; the enunciation of the great principles of immunity, both "active" and "passive"; the preparation of vaccines and of antitoxic serums and their use in the prevention and treatment of bacterial infections; the therapy of systemic infections by the intravenous introduction of chemical antiseptics resulting, among other notable gains, in that brilliant conquest of the former scourge of syphilis that has been achieved within the present century—all of which constitute milestones along the highway of bacteriology's triumphal progress.

Nor have I time to refer to the great help that modern surgery has received from research workers in anatomy, pathology, and pharmacology, valuable as their contributions have been; nor yet to more general sources of assistance such as the greatly improved means of rapid intercommunication—the telephone, the wireless—and of rapid transport—the motor-car, the aeroplane—factors which have so materially facilitated the prompt application of surgical relief in cases of emergency, whether on land or at sea.

I trust, however, that enough has been said to indicate that modern surgery, with the aid of its allies, has made and is still making great progress towards that end we all so fervently desire—the prevention of those abnormal conditions, the late results of which to-day necessitate so much surgical attention of a destructive rather than a constructive character. Much yet remains to be done, and the natural sciences must continue to advance, each ready to assist and to accept assistance from its fellows, each along its own special path yet all in mutual friendly alliance working for the common good, all in zealous pursuit of that goal, unattainable though it must ever remain, that will-o'-the-wisp of perfect knowledge and complete understanding. In so doing they will but follow the precept and the spirit of that motto upon the crest of our beloved University, in whose venerable precincts this great Association will to-morrow enter upon its full scientific programme, and of which we in this city are all so intensely proud: "Arduus ad solem"—"leaping upwards to the sunshine"—"ever striving towards the very highest."

PHYSIOLOGY THE BASIS OF TREATMENT.*

BY

W. E. DIXON, M.A., M.D., F.R.S.,

READER IN PHARMACOLOGY, UNIVERSITY OF CAMBRIDGE.

THE ultimate aim of medicine is the prevention or cure of disease: this practical aspect so far dominates all others that it is often referred to as the healing art; indeed, it is difficult to think of medicine apart from treatment.

The term "physiology" is usually used to designate the science of function, whether it is studied in broad outline and dealing with the mechanism of action or as the physico-chemical mechanisms leading up to this action. Disease means the unusual functioning of tissues which may be the result of accident, hereditary weakness, or parasitic organisms. Generally it is wrong to speak of this as malfunctioning: the unusual functioning is physiological and perhaps the best for the organism under the unusual conditions. The science of medicine, then, is nothing more than trained and organized common sense based on physiology. It is still usual to speak of it as an inexact science; this is obviously wrong, since medicine uses the same methods as every other science, and the results of observation are as definite as those of the chemist or physicist; although it is true that, in the complexity of the problem with which the physician may have to deal, all the conditions of importance may not be known, and the results of an investigation, though correct for the conditions under which it is undertaken, may be misleading.

When the sciences of physiology and pathology a century ago passed from the realms of natural history to deduction and experiment, they naturally attracted the more original and eager minds in medicine, and the text of the writings of the nineteenth century deals with changes in structure and function. Treatment became neglected, the old shibboleths and rituals of treatment which had held sway for centuries were discarded, and there was nothing with which to replace them. In the middle of the last century S. Skoda and K. Rokitansky perfected a system of physical diagnosis which has had a practical bearing on medicine ever since. Skoda made many experiments with drugs on the patient without any expectation of producing benefit; the patients were not improved and Skoda thought it mattered little how the patient was treated. Scientific medicine looked askance at treatment; textbooks spent many pages in describing the symptoms, diagnosis, and pathology of disease, but two or three lines dismissed the treatment: and even in our times the "scientific" physician is apt to be a diagnostician rather than a healer. The study of disease as an entity was the object aimed at, and a complete case was one which went to autopsy. This state of affairs was unavoidable; there was no specific treatment, there was no science of treatment, for such a science could only come into existence when physiology and pathology had reached some degree of

* Abstract of Presidential Address delivered on July 24th at Capetown before the Section of Physiology, British Association.

precision. Diagnosis was then, and is now, far ahead of treatment: diagnosis is often accurate where there is no satisfactory treatment, and yet diagnosis is only a means to the end.

The science of treatment or pharmacology is the climax of physiology and pathology, devised to subserve a practical end, and forms an important part of the great biological topic of the influence of conditions on the living organism. Few drugs now exist the mode of action of which is not understood, and the goal is not so far distant when it will be possible to introduce into the animal economy a factor which will exaggerate or retard the function of any tissue or collection of cells in the body, leaving the others unaffected; and most of these results have been obtained by the methods used in experimental physiology.

The first object of science is to ascertain facts: certain facts in physiology are relatively easily ascertained—those, for example, which involve the behaviour of ferments of isolated cells or of tissues and which require well-known chemical or physical methods. Other facts involving the physiology of the whole organism are more difficult to interpret, though they are the basis of the therapeutic side of medicine. More and more is physiology being regarded as the application of physics and chemistry to the phenomena of life. The modern attitude is expressed by a distinguished young biochemist who, in reviewing a well-known book on chemotherapy in 1928, asks, "Might not the time and resources spent on chemotherapeutic research be diverted more profitably to the study of chemical and physical mechanism?" The same attitude is reflected in the awards of fellowships and scholarships for medical research. Formerly all the recipients were primarily biologists with a medical training; now a medico-biological training is unusual. Physiology in the broad sense in which it was used by Claude Bernard and Huxley has given place to a new physiology of physico-chemical reactions: I might go beyond this and say that physiology is getting further and further from practical medicine, and this is the more regrettable as most of the chairs in physiology are connected with the medical schools and because the science of treatment is largely dependent on experimental physiology.

Pharmacology and Therapeutics.

No branch of experimental biology has received less consideration in Great Britain than that of pharmacology: it is also the most neglected branch of medicine, and although the object of medicine is the healing of the sick, it is amazing that medical schools in Britain, often equipped with all other modern laboratories, lack departments of therapeutics. I was once asked at a meeting, by a leading medical man, what has pharmacology ever done? The answer is, *of course, that it has formulated* and brought reason and knowledge into treatment of the sick; so much did it impress that great pathologist Ehrlich that he left his serums and turned his attention to drugs, and with the unlimited resources at his disposal gave the world, amongst other drugs, salvarsan; so much did it impress the brilliant French chemist M. Fourneau that he has confined his studies to those of drugs, a study which has resulted in the synthesis of many valuable arsenical compounds and dyes.

I have heard it said by a leading official of our Ministry of Health, speaking to panel practitioners, that they, in the Ministry, do not want stereotyped prescribing in treatment. Surely there was never such nonsense. If there is a best treatment, let us have it, whether it is stereotyped or not. In this respect the British Medical Association has given the profession a lead, and shown by the experience of a great number of doctors that there is a best way of treating varicose ulcer in which the patient gets well quicker than by other ways, an advantage both to the patient and to the community who have to keep him whilst he is unfit for work.

The British physician is a skilled diagnostician and is in the forefront in all that pertains to this subject. The literature is so extensive that it is impossible for the average clinician to do more than this. But how few of them do, or perhaps the more correct word is "can," occupy the same time in the study of recent advances in general therapeutics! The successful physician has, generally speaking, to be content with such references to treatment as are to be found in clinical reading. The general physician must always be a necessity for diagnosis; but the details of treatment of patients will, I believe, in the future be handed over to those who have made a special study of the treatment of that particular group of diseases from one of which the patient is suffering.

It has been often said that the action of remedies may be best determined by experimenting with them on healthy men. This is not true; quinine is used to treat malaria, yet not one of the subjective symptoms induced in man has the remotest connexion with its curative properties. The same is true of the use of the iodides in syphilis and salicylates in rheumatism. The experiments of Joig and his pupils in 1825 with camphor, digitalis, and other drugs on healthy men added nothing of value to pharmacology. Subjective sensations are, it is true, produced, which are erroneously attributed to the drug which has been taken. The late Dr. Rivers and myself were nearly the dupes of such an experiment, which I will give in full because it illustrates the imaginary sensations and effects produced by S. Hahnemann and his pupils, by Perkin with his retractors, and by more modern physicians with their mystic apparatus.

> Our experiments were made on healthy men under a regular regime as regarded sleep, exercise, and diet. The men were practised with the use of the ergograph during several weeks at the same hour daily, until their output of work was constant. We found that the administration of a dose of caffeine dissolved in water one hour before the experiment greatly increased the output of work for that day. This was repeated on several occasions, always with the same result, and we naturally regarded the effect as due to the caffeine. This, however, was not the case: the effect was due to the ritual of taking a drug; the drug day assumed an enhanced importance in the mind of the operator, and the mental effect sometimes referred to as suggestion was principally responsible. We had no difficulty in showing that water made bitter with a trace of quassia or other simple bitter had a similar effect.

Few, if any, experiments made on man without the most careful controls are of any real value. Properly controlled experiments have been made, however, with many substances. Precise experiments, for example, have been made in both Germany and America with bromides in epilepsy. In these experiments half the epileptics were given potassium chloride and the other half sodium bromide; after several weeks' use the bromide had decreased the number of attacks, whilst the chloride had no distinct action.

Chemotherapy.

At one time hopes ran high that the chemical structure of the molecule might indicate pharmacological action. During the last fifty years many laborious researches have been conducted with this object: to modify the molecule that it may conform to some required action. But the mystery remains as mighty as ever. It is most probable that subtle energy factors binding the molecule—factors not displayed in a formula—control the action; certain it is that drug action is not determined directly by chemical combination with body constituents, but rather by delicate physical processes such as those of adsorption, solution, and surface tension. Chemists have as yet not even determined the requirements of the molecule for the production of colour sensation. On the other hand, slight alteration of a molecule already complicated and with a known action has led to the production of many useful compounds, and not infrequently we may foresee the type of action which will occur under such special conditions. Considerations of this nature have led to the synthesis of the new local anaesthetics, antiseptics, antipyretics, diuretics, tropeines, and other useful substances.

But chemistry has taken yet a further step in its assistance given to medicine in the development of that branch of science to which the name chemotherapy has been given. Ehrlich noticed that colouring matters injected into the living organism had a selective affinity for certain cells, and he believed that it might be possible, by making use of

this property, to select suitable substances which would destroy the causal agents of disease—parasites and microbes—and leave the tissues of the host uninfluenced. Parasites causing disease in man may be crudely divided into worms, protozoa, and bacteria. Chemotherapy—that is, specific therapy of infectious disease—has had marked success in curing disease due to parasites in the first and second of these groups; these diseases are found mainly in the tropics. It has obtained much less success in the third group.

Diseases due to protozoa have a special significance in Africa, and it is appropriate that in this meeting some reference should be made to that area of tropical Africa occupying more than a million square miles in which one form of these—namely, trypanosomes—produce their ravages. Two forms of trypanosomes are known to infect man, *T. gambiense* and *T. rhodesiense*; the latter is more rapidly fatal than *T. gambiense*, and its treatment is less satisfactory. *T. gambiense* is transferred by *Glossina palpalis*, *T. brucei* by *G. morsitans* and *pallidipes*, and *T. rhodesiense* by *G. morsitans*. Besides the human form of the disease another tsetse fly is responsible for the trypanosomes of domestic animals, including horses and cattle, *T. brucei*, which produces the disease n'gana, so that in infected districts draft animals and dairy cattle cannot exist. Trypanosomiasis is one of the most serious of all tropical diseases, and affects both man and beast; it is a scourge which renders vast tracts of land practically uninhabitable, and which takes its death toll even in thousands, and occasionally even in hundreds of thousands, and yet it is a disease which I believe should be curable, if not preventable.

The members of two groups of chemical substances excel all others in their curative value in trypanosomiasis and spirochaetosis; these are the organic arsenical compounds and the dyes. The specific action of organic arsenic compounds really begins with some observations of Thomas on the action of atoxyl on trypanosomes. Ehrlich had previously discarded this substance because it was without direct action on the protozoon, but later he observed, like Levaditi and Mesnil, that in infected animals it had a more pronounced action than that of any other substance up to then employed. Atoxyl was, however, soon discarded as a curative remedy, because it caused permanent and complete blindness in some cases. Acetyl-atoxyl, known as arsacetin, which was at one time widely used, had no better fortune, and several cases of permanent blindness resulted from its use. Ehrlich's experiments with Hata, in which innumerable arsenical compounds were employed, led him to select salvarsan as the best; in this substance the nitrogen and arsenic are in the meta position, and not in the para, as in atoxyl. This substance as a treatment of syphilis and other spirochaetal infections stands as firmly to-day as it did ten years ago; it has one drawback—it does not influence the condition of the patient if the central nervous system is attacked. Other substances, like tetramethyl hexamino-arsenobenzene (arsalyte Giemsa), have been produced which are also very efficient in spirochaetosis.

The most satisfactory arsenic compound yet discovered for the cure of trypanosomiasis is tryparsamide. It is less toxic than atoxyl, and has a slightly higher therapeutic index; it has a most marked trypanosidal action in animals, and has been used with some success in cases of sleeping sickness from *T. gambiense*. One injection causes the disappearance of the parasite from the blood of man, and if the injections are repeated in courses the cure may be complete. Like atoxyl it affects the eye: even the smaller therapeutic doses cause visual disturbance, and the risk of complete blindness is always present; perhaps as many as 30 per cent. of all patients treated with this drug suffer from some eye lesions. Tryparsamide is valuable also in certain forms of syphilis, particularly cerebral syphilis: approximately 40 per cent. of the cases of general paresis committed to the State Insane Hospitals in Wisconsin were restored to sanity (Loevenhart). This action is probably indirect, since there is no evidence to show that it is absorbed into the central nervous system more than other organic arsenicals.

All these organic arsenical compounds must be injected in order to produce a satisfactory effect; but one compound, m. amino-p. hydroxyl phenyl arsenic acid, acts upon and destroys spirochaetes when taken by the mouth (Levaditi); it is generally administered as its acetyl derivative, which is known as stovarsol. Stovarsol has been largely used as a preventive to syphilis, but it is now known that it has a remarkable curative action in amoebic dysentery like emetine (Valenti), and that in cases of benign tertiary malaria it checks the attacks and prevents the return of the disease, at all events for many months.

It was at first thought that, as laboratory animals are so easily infected with trypanosomes, it should be an easy matter to determine which compounds were likely to be most valuable in the treatment of trypanosomiasis. Unfortunately this is not the case; a drug may cure trypanosomiasis in one animal and not another, and the crucial tests must always be made on man.

Most of the antimony derivatives corresponding with the organic arsenicals have been prepared; for example, that corresponding with acetyl-atoxyl, also m. chloro-p-acetyl amino phenyl stibamate of soda (Heyden 471) have been extensively employed in kala-azar and bilharzia. Speaking generally, they have a more powerful action than tartar emetic on such diseases as bilharziasis, kala-azar, and filariasis, and to some of them, like sodium antimony thioglycollate, the parasites do not become readily immune. Unfortunately the organic compounds of antimony have a toxic action on the tissues, and are very difficult to administer, so that antimony tartrate or stibamine urea, a compound which has recently been prepared pure, are generally preferred.

DYES.

Many dye substances have been used in medicine: as they are readily adsorbed on to cell surfaces the concentration here is always high, and the surface properties of such cells are often modified in consequence. One general principle which follows from this is that widely different dyes often possess properties in common—for example, that of being antiseptic. To-day I propose to refer only to one group, the benzidine dyes.

Trypan red and trypan blue belong to this group. Trypan blue was employed by my colleague Professor Nuttall in piroplasma infections in animals, with results that most South Africans are well acquainted with. Afridol violet, a derivative of diamino diphenyl urea, and some allied dyes have also a powerful action on piroplasma. How these substances act is not known, for like the organic arsenicals they do not kill the parasite *in vitro*. They have the property, however, of being adsorbed to the blepharoplast of the trypanosome; this adsorption is associated with diminished virulence of the parasite in infected animals, and after successive inoculations through several animals the organ may disappear. This direct action of a drug on a tissue, causing ultimately the complete disappearance of that tissue, is so remarkable that it is worthy of notice, as it represents the first known action of the kind. The most valuable member of the afridol-violet group so far produced was first made in the Bayer laboratory, but its composition was kept secret. It was, however, subsequently synthesized and its formula published by Fourneau, but only after long trials and infinite patience. Fourneau has made many allied substances and derivatives of "205"; the number of such derivatives is obviously legion, and this makes it the more remarkable that he should have succeeded in synthesizing "307," which at the present time is superior as a therapeutic agent to all other dyes in trypanosomiasis. This "307" has a remarkable action on trypanosomes in laboratory animals, being 300 times more effective than atoxyl. Its discovery has also opened a new era in therapeutics, since it represents the first chemical substance which, when administered to man or animals in an infected trypanosome district, gives a complete immunity to the disease for several months; it does not necessarily prevent trypanosome infection, but it prevents the effects of the disease. There is much in these experiments that suggests that we are on the fringe of a new pathology, and that our present crude methods of preparing antibodies in the future will be replaced by those of the organic and colloid chemist.

In man "205" has not done all that was expected of it; it invariably benefits those that show infection and enlargement of glands—that is, during the early stages of the disease—and its value is also assured even when the nervous system is affected. If care is taken in the treatment, and a series of injections given at not too frequent intervals to prevent the parasite acquiring a tolerance, and if the patient is kept under observation for a prolonged period of time, the happiest issue may be anticipated; "307" is much less valuable on n'gana in animals.

Bacterial Infections.

Much the most important industrial disease in South Africa is the silicosis produced in the extraction of gold from the conglomerate, both the pebbles and the matrix consisting of quartz. The gravity of pneumoconiosis depends largely on superadded tuberculous infection, to which the workers have a predisposition, and in this respect crystalline silica is much more harmful than either amorphous silica or carbon.

The report of the Miners' Phthisis Medical Bureau, dealing with the years 1914–26, shows that the incidence of silicosis is increasing. Of the average number of 178,000 natives employed on the scheduled mines during the year 1925–26, of whom 133,260 were employed underground, simple tuberculosis was found to be present in 566, simple silicosis in 231, and tuberculosis with silicosis in 446. Workers employed in other dusty trades, such as the preparation of asbestos materials, also suffer from pulmonary disability, and Dr. Collis found that five deaths from phthisis had occurred in five years amongst a staff of less than forty workers employed in a factory where asbestos was woven; asbestos contains about 50 per cent. of silica. The dust associated with the process of carding, before its extraction was efficient, at one time in England produced a pneumoconiosis resembling that of silicosis. It is well recognized that a patient suffering from tuberculosis who is placed under treatment will, for a time at least, improve in health, no matter what drugs, vaccines, or "specialties" may be employed. The beneficial result is due, in this as in other disease, to efficient nursing, to the regulation of food, exercise, and sleep, and to light and fresh air. General hygienic measures are of primary importance in treatment, and it is not until all the beneficial effects which are known to ensue from these have been exhausted that the physician has any right to ascribe an effect, beneficial or otherwise, to a special treatment.

Drugs are employed in tuberculosis either with the object of attacking and preventing the growth of the tubercle bacillus or other organisms with which the disease may be associated, of neutralizing poisonous toxins, or of removing or relieving symptoms. It is with the first group that I am now concerned. Two groups of organic compounds are especially remarkable for their chemotherapeutic action on bacteria. The first group has the quinine complex: the action of optoquin on the pneumococcus and of vuzin on *Bacillus diphtheriae* is highly specific; the higher and lower homologues have a greatly diminished effect. Many substances destroy bacteria in the test tube, but these drugs act in the animal body as well as in the test tube, and enough can be given by medicinal doses to animals and men to render the blood of these animals bactericidal.

The second group of drugs which exert a marked action on bacteria are certain derivatives of acridine. Trypaflavine was used during the war for infected wounds; unlike most antiseptics, it acts better in the presence of protein, but is not sufficiently selective or specific on micro-organisms in the presence of body tissues to be of any real value; it is easily absorbed, and readily causes oedema. Rivanol is a more recent derivative of acridine. Morgenroth cured streptococcic infections by injections of rivanol under the skin. The injections to be efficient must be made soon after the infection and in the neighbourhood of the inoculated zone; rivanol will not cure a blood infection. Its discovery is, however, a great advance over any substance previously available in this group, and we can anticipate with some confidence in the near future the introduction of other derivatives which will destroy acute infective agents.

Two other chemical substances are worthy of consideration for the remarkable effects accredited to them in the treatment of microbial infections—mercurochrome and hexyl-resorcinol. Clinical evidence shows that mercurochrome exerts a curative effect, especially in the case of streptococcic and staphylococcic infections, and these effects have been repeated in animal experiments. Hexylresorcinol has a phenol coefficient of 72, and it renders the urine in which it is excreted germicidal; many reports show that it effects remarkable cures in cystitis and pyelitis. Unlike mercurochrome, the action of this substance, at least in the urine, may be direct on micro-organisms.

The chemotherapeutic substances which are known to act on bacteria are without value in tuberculosis. Thus flavine and its silver salts do not influence the tuberculous process in living animals, and the same is true of the quinine derivatives which have been prepared so far. The destruction of the tubercle bacillus presents two special difficulties: first in the fatty and protective envelope surrounding the bacillus, and second in the small blood supply to the tuberculous lesion. Success, however, has been claimed for several metallic compounds, and I shall confine my remarks to three of these. It is by no means clear that the results which have been obtained by administering gold salts to tuberculous patients or animals are superior to those given by copper salts, which preceded them. "Krysolgan" was introduced by Feldt; it prevents the growth of the tubercle bacillus in cultures in 1 part in 1,000,000. Nevertheless, animal experiments with this substance are not promising, though the clinical results published in Feldt's monograph in 1923 are certainly both helpful and inspiring.

Another "gold" cure is that recently introduced by Moellgaard. It is a double thiosulphate of gold and sodium, which, although a well-recognized substance, he calls "sanocrysin." Like its predecessors, it retards growth of the tubercle bacillus in glycerinated bouillon in such strengths as 1 in 8,000,000, but how serum added to the cultures affects its action I have not discovered. Nevertheless, this is a very important point, since such chemotherapeutic substances as exert an undoubted action on bacteria invariably act the better in the presence of the tissue fluids. Moellgaard assumes that his gold injections destroy the tubercle bacillus *in vivo*, and states that doses which are not poisonous to normal animals kill the tuberculous animal by producing a tuberculin shock. This shock begins with an albuminuria and sometimes haematuria; it is followed by toxic myocarditis and pulmonary oedema. There is, however, no clear evidence to prove that the shock in tuberculous animals after an injection of sanocrysin is due to the destruction of tubercle bacilli and the setting free of endotoxins, which act as tuberculin acts on tuberculous animals. Another feature of importance in these experiments is that the cultures used were attenuated. The doses necessary to kill were enormous, and many control animals failed to die or contract severe disease.

Hoyle and I have recently investigated two new types of gold compounds in tuberculosis. One of these is a complex aurous salt of ethylenethiocarbamide with the formula $(Au,2etu)H_2O$, where etu represents ethylenethiocarbamide. It was tested for therapeutic effects on both human and bovine types of infection. For the former, inoculations were made subcutaneously into guinea-pigs with 1-mg. doses of a virulent human strain. All the animals, control and experimental groups, died within a few days of one another, and all showed characteristic progressive lesions of similar extent. It was found that treatment with the gold compound in bovine disease in rabbits prolonged life about 50 per cent. when compared with controls. We adopted the arbitrary standard that treated animals should survive at least two or three times longer than the average length of life of the controls before clinical trial should be proceeded with. In view of the wide variations in individual susceptibility, and the difficulty that this entails in drawing sound positive conclusions from a small series of animals, it is absolutely necessary to exercise the utmost caution before arousing clinical expectations.

The second compound tested by us was a complex gold derivative of succinimide, prepared by my colleague Sir William Pope. This substance was tested for therapeutic effect in experimental bovine infections in rabbits. In some animals this treatment was supplemented by injections of potassium iodide subcutaneously; in no case have any therapeutic benefits been observed. There has been no increase in the lengths of life of the treated animals, and the type and extent of disease at post-mortem examination in treated and control animals has in every case up to the present been similar.

These compounds are interesting because the one delays death and the other is entirely without action. They may afford a hint as to the lines on which organic chemists should proceed, and perhaps show that gold in the ionic form is desirable.

THE INTERNAL SECRETIONS.

In the last twenty years much evidence has accumulated to show that the glands of internal secretion are responsible for the regulation of growth, of metabolism, and often for our appearance if not for our very character. Exaggeration or diminution in the secretion of one or other of the tissues may induce conditions so decided as to be obvious to everybody, though the effects produced by minor alterations in the co-ordination of the several secretions may not be so evident. Giants and dwarfs, unusual pigmentation and anaemia, disproportion in the growth of the skeleton, such as enlarged hands and face, bulging deer-like eyes or oriental eyes and beards in women are noticeable to everyone; excessive fatness or emaciation, a choleric or bucolic temperament cause no comment, yet may equally arise in the victim from a want of co-ordination in the internal secretion.

The general outlook and significance of drug therapy was led into new channels when it was revealed that the animal body through these glands elaborates its own drugs, stores them generally at the seat of formation, and doles them out to the tissues to meet the needs of the economy. Some of these drugs are of the nature of alkaloids comparable with those elaborated by plants. It is a remarkable fact that when Nature elaborates a drug in either a plant or an animal, that drug is invariably the ideal drug for producing the action for which it is characteristic. No drug relieves pain like morphine or produces local anaesthesia so well as cocaine; no drug paralyses the parasympathetics so perfectly as atropine or the motor nerves so effectively as curarine; strychnine supersedes all other drugs in exaggerating spinal reflexes, and caffeine in its remarkable power of stimulating the psychical centres of the brain. Of the animal drugs, adrenaline has a superlative effect on the sympathetic system, pituitary on the uterus, and thyroxin on general metabolism.

The Suprarenal Gland.

The suprarenal gland is composed of two distinct organs. The medulla elaborates an alkaloid named adrenaline, the action of which corresponds with stimulation of the entire sympathetic system. What exactly its functions may be in the animal economy is not certain; its output under normal conditions is so limited that it can hardly affect the blood pressure and it is not apparently essential for life. There can be little doubt, however, that in moments of excitement adrenaline is liberated in large amounts and that it is responsible for some of the expressions of the emotions. The action of adrenaline under such conditions is to raise the blood pressure by constricting peripheral vessels, to dilate bronchioles, to erect the hair, to increase the blood sugar, to immobilize the alimentary canal, and to facilitate the clotting of blood. Cannon has shown that cats respond to psychical stimulation, such as may be induced by the presence of a dog, after the entire thoracic sympathetic system has been removed; the interpretation must be that in these emotional conditions adrenaline is set free in relatively large amounts.

The expressions of the emotions, such as anger and terror, are to the animals an advantage: the easy breathing, the ready clotting of the blood, the increased circulation may all have their advantages in a fight. The ultimate cause of spasmodic asthma is constriction of the bronchiolar muscle; if during an asthmatic attack the patient is subjected to some sudden terror or other pronounced emotion the attack sometimes promptly ceases, in a manner exactly simulating the way in which a small injection of adrenaline will abort an attack.

In parts of West Africa the calabar bean, *Physostigma*, was sometimes used, in trial by ordeal, to determine the innocence or guilt of persons accused of witchcraft or other crimes. A normal person, after drinking an infusion of this bean, promptly vomits and gets rid of the poison. In states of emotion, which might well occur in a guilty person, the stomach is flaccid and immobile, vomiting does not occur, and the poison is absorbed. The adrenaline takes some part in this inhibition of vomiting as it stops the movements of the stomach. The bean ordinarily induces violent contractions of the stomach which cause reflex vomiting.

Ephedrine is an alkaloid which has been used by the Chinese as a medicine from time immemorial. It is closely related to adrenaline and has an action very similar to it; but ephedrine acts when taken by the mouth, while adrenaline is so easily oxidized that it is destroyed when administered in this manner. Adrenaline causes pulmonary congestion by dilatation of the coronaries; ephedrine has no such effect. Ephedrine has proved of great value in the treatment of spasmodic asthma, since oral administration produces prolonged broncho-dilatation.

The Parathyroids.

Another striking result from experimental work in the field of internal secretion has recently been obtained in the case of the parathyroid glands. Many vague and unsatisfactory statements existed in the older literature as to the functions of these bodies; but now a potent extract of bovine parathyroid glands accurately standardized can be obtained, and precise knowledge of the part these glands play in the animal economy has become possible. Extracts when injected into a variety of animals raise the level of the blood calcium; if the injection is made into an animal that has been previously parathyroidectomized, tetany and the usual fatal outcome are prevented. Repeated or very large doses in normal animals produce a condition with a definite clinical and biochemical picture—a condition of "hypercalcaemia," in which the blood calcium may rise to very high levels and in which a characteristic train of symptoms is found with terminal renal failure. All this work has shown beyond doubt that the parathyroid glands produce a substance which is responsible for controlling the level of blood calcium, and that interference with this function by removal or disease of the glands can be overcome by treatment with the potent extracts now available.

The Ovary.

The gonads present the clearest evidence of the influence which a tissue may exert on metabolism. I will refer only to the ovary. Virchow is reported to have said that all the peculiarities of the body and mind of woman, all which in the true woman we admire and revere as womanly, are dependent on the ovary. Knauer showed that this organ was intimately connected with oestrus, and that ovarian grafting could at least partly antagonize the effects of spaying. This ovarian action can be produced in both sexes. If a portion of an ovary is grafted into a castrated male animal the mammary glands and teats hypertrophy, the glands develop to the secretory stage, and the animal comes to resemble a pregnant female: males so grafted become hyperfeminine in appearance. In the male the development of the mammary glands is uninterrupted, the Graafian follicles mature but do not rupture, and the ovary soon degenerates. In the engrafted female development is slower and, unlike the male, shows a rhythm which is associated with the development of the Graafian follicle, and in the regressive phase with its rupture and the formation of the corpus luteum.

The ovary does not function till puberty, and there is considerable evidence to show that this is brought about by some internal stimulus. A young ovary grafted into an adult male or female will begin its secretion sooner than its age warrants, whilst an adult ovary engrafted into a young animal will not function until the animal reaches maturity. This fact is of practical importance, since in cases of infantilism it is not necessarily the ovaries which are at fault, and ovarian transplantation may not improve the patient. The ovary differs from other organs of internal secretion in that it functions in a cyclic manner, and it is obvious that extracts made from ovarian tissue may exert a different action according to the period of the cycle when they are made.

Numerous extracts have been prepared from the ovary which are reputed to exert one or other type of action. "Oestrin", is the name given to one such substance; it can be made from many sources, both animal and vegetable, besides the ovary. Oestrin exerts a very definite action in lower animals, but its use in man is so variable and disappointing as to make it valueless in practical medicine. When it is injected subcutaneously into spayed rats and mice it produces typical oestrus with normal sex instincts, and when injected into immature animals it induces puberty; regular injections at fixed intervals will keep animals sterile.

Many experimental observations show that the corpus luteum is concerned with the rhythm of the oestrous cycle and with the prevention of ovulation. A persistent corpus luteum, in both animals and women, produces sterility, a condition which is cured by its removal. The presence of fully formed corpora lutea appears to inhibit some ovarian secretion, and this condition obtains in animals for a time between the heat periods, but more particularly during pregnancy. In women there is plenty of pathological evidence to show that functional corpora lutea are not present during menstruation. If the corpora lutea exert this controlling action on ovarian function, then their removal should release the normal ovarian function; such operations during pregnancy are invariably followed by abortion. On the other hand, injections of properly prepared corpus luteum prevent ovulation; this has been shown in the case of the hen, the rabbit, and the guinea-pig.

Interstitial Hormone.

A third active substance distinct from oestrin and corpus luteum is elaborated from the ovary, and was described by Marshall and myself. The substance is water-soluble and therme-stabile, and can be prepared from the ovary at one stage of its cycle only, by maceration with warm saline, followed by boiling and filtering. The injection of this substance into animals causes a secretion of pituitrin, and this in turn renders the uterus supersensitive and highly responsive to other forms of stimulation.

The pituitary gland is intimately connected with the phenomenon of pregnancy; statistics show that the size and weight of the gland in men and nulliparae are about the same; in primiparae the weight has increased by about 50 per cent., and in multiparae by about 90 per cent., though most of the increased weight is due to the anterior lobe. The posterior pituitary substance has at least three actions of importance in medicine: it inhibits the secretion of urine, it has an antagonistic action to the insulin effect, and it sensitizes and, in larger doses, contracts the plain muscle of the uterus. The last action is so profound that it overshadows all the other muscular effects, and pituitrin may be said to have a true specific action on uterine muscle in rendering it supersensitive to every form of extraneous stimulus. Our experiments showed that at one stage only of the ovarian cycle was this hormone elaborated —namely, at the stage when the corpora lutea are degenerating. So long as the corpora are functioning they control the metabolism of the ovary, but when they degenerate control is lost and the ovary liberates the specific substance which excites the pituitary gland to secrete. This means that extracts of the ovary made between the heat periods or during pregnancy are without effect on the pituitary gland, but extracts made just before the heat period or just before parturition induce secretion of the gland. As the significant action of pituitary extract is to sensitize the uterus it is difficult, if not impossible, to avoid the conclusion that these two phenomena are closely associated.

It is well known that substances introduced into the cerebro-spinal fluid find their way almost immediately into the blood, and hence it might be expected that extracts made from the blood of pregnant rabbits obtained at the time of delivery would have a contractile influence on the uterus; this has been found to occur. Similarly, blood obtained from pregnant women at the time of delivery contracts the guinea-pig's uterus to a considerably greater degree than normal blood. Mayer collected the cerebro-spinal fluid from women during Caesarean section. This fluid he injected subsequently into ten women with deficient labour pains. In eight of the women pains were induced, which in four were followed by the birth of the child. In another case an intradural injection was made, which was followed by labour pains within twenty-four hours. The interaction of bile salts and pituitary secretion is antagonistic on the uterus. Hofbauer shows that there is a steady increase in the bile salts in the blood of pregnant women as gestation proceeds. He thinks that this factor is responsible for the control of the pituitary secretion during pregnancy, and that towards the end of labour the pituitrin action overshadows the bile-salt action, so that labour occurs.

All these experiments consistently support the view that in the presence of fully formed corpora lutea the normal ovarian secretion is held in abeyance, and this is the condition for a short part of the time between the heat periods, but more particularly during pregnancy. At the close of pregnancy, when the corpora lutea are in an advanced stage of involution, the normal secretory activity recurs, and the pituitary gland is excited to secrete more actively. When the threshold stimulus of the pituitrin on the uterus is reached the pains of labour set in and parturition results. The well-known phenomenon of the growing irritability of the uterus in the later stages of pregnancy, which is the typical effect of the pituitary action, is explained as being functionally correlated with the involution of the corpus luteum. It is not suggested that the ovario-pituitary endocrine mechanism is the sole factor in producing labour pains. No doubt the foetus itself acts as a direct stimulus, and without the foetus the intense muscular contractions would not occur, but it is also clear that the onset of labour cannot easily be accounted for without postulating some further exciting cause apart from the foetus and the uterus. No romance can be more remarkable than the fact that doctors, by using pituitary extract to stimulate the uterus in pregnancy, should have adopted the method which Nature herself employs, and that physiological function is, after all, a pharmacological action.

Concluding Remarks.

I have endeavoured to show that all precise knowledge in therapeutics is based upon controlled experiments on animals or man, and that the elucidation of the action of medicaments by the methods and data of experimental physiology is one of the most important steps taken to place medicine on a scientific basis. How important this is may be gauged from the fact that all fundamental advances in treatment in the last thirty years have originated, directly or indirectly, from experiments on animals. There can be no doubt, then, that the future of therapeutics, and therefore of medicine as a whole, is intimately connected with physiology; there can be no doubt that advance in the practice of medicine is dependent on those trained in the methods and fundamental truths of physiology, who devote themselves in the ward and biological laboratory to investigating how best to prevent or cure disease, and so relieve suffering.

Britain for fifty years has every reason to be proud of her progress and achievements in physiology; it is acknowledged that she can show records second to none, and that her savants have included some of the world's greatest investigators. It remains for us to hope that in the future she may attain equal success in the associated sciences directly concerned with the relief of suffering and cure of disease.

TRAUMATIC RUPTURE OF THE STOMACH

BY

F. HECTOR SCOTSON, M.B., B.S.LOND., F.R.C.S.ENG.,

LATE RESIDENT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY.

IN the *Glasgow Medical Journal* of 1894, J. Grant Andrew, in a paper read before the Glasgow Pathological and Clinical Society in December, 1893, reports a fatal case of traumatic rupture of the stomach due to a crush, for which no operation was performed. In his review of the literature, he states that up to 1858 three cases of complete rupture of the stomach had been reported, and, including the one he related, there were eight further ones up to 1893. All these cases were fatal, some immediately following the injury, two being five days after the injury. He makes a note that the rupture was generally near the pylorus, and that vomiting was frequent in most of the cases.

In *Acute Abdominal Diseases*, published by Adams in 1923, it is stated that rupture of a normal stomach may be caused by violent contraction of the abdominal muscles, by blows, or by crushes. He states that the rupture is usually longitudinal, and near the pyloric portion of the lesser curvature of the stomach, and the only pathognomonic signs are fresh blood in the vomit and obliteration of the liver dullness—in addition, of course, to the usual signs of rupture of any abdominal viscus.

Sherren states that between the years 1899 and 1919 eleven cases of ruptured stomachs were admitted to the London Hospital, but in only three was it the sole viscus ruptured, and all these cases treated in the London Hospital died. He says that ruptures from external violence are usually situated in the region of the greater curvature. He also quotes Deaver and Ashurst as stating that only four operations for traumatic rupture of the stomach have been recorded, and all resulted in death.

Walton, in his *Surgical Dyspepsias*, states that traumatic rupture of the stomach is rare, and generally other viscera are affected. He quotes Sherren as saying that of 270 cases of abdominal contusion admitted to the London Hospital in ten years the stomach was ruptured in five, and in only one of these cases was no other viscus affected. He also quotes Battle, who published 165 cases of intestinal injury, but no example of injury to the stomach. Walton states that practically all reported cases of rupture have occurred when the stomach is full, and that rupture takes place at the weakest part of the wall—namely, the greater curvature. Owing to the severity of the injury and the frequency of the accompanying lesions these injuries are nearly always fatal.

I thought it would be interesting for me to publish (with the kind permission of Professor Burgess and Mr. Wrigley, under whose care these patients were while at the Manchester Royal Infirmary) two cases which I operated on, and in which the rupture of the stomach was the only abdominal injury present, and both of which made uninterrupted recoveries, each patient being discharged from the Infirmary in a fortnight.

CASE I.

Mrs. J. G. was admitted to the hospital on July 14th, 1928, following the injuries she received by her car colliding with another one, the impact doubling her up and throwing her under the dashboard. When I examined her she was pale, she had vomited once following the accident, the abdomen was rigid, she was suffering severe abdominal pain, and there was diffuse tenderness and guarding all over the abdomen, more especially at the right side. There was no shifting dullness to be detected in the flanks. Her pulse rate was 92, and temperature 99° F. There were no other signs of injury anywhere to be made out. On the diagnosis of the rupture of an intestinal viscus, I made a right rectus slide incision, and on opening the peritoneum I found blood and extravasated contents in the abdominal cavity. These were swabbed out, and rupture about the size of a threepenny piece was found at the pyloric end of the stomach near the lesser curvature. The rent was sutured with interrupted Lembert sutures of catgut, and the abdomen was then closed, with drainage to the abdominal wall. She was discharged home on July 28th.

CASE II.

Mr. A. F. was admitted to the Manchester Royal Infirmary on December 18th. He could not give any account of the accident; as he was suffering from some slight degree of concussion of the brain. I learnt from witnesses that he had been knocked off a pedal cycle by a motor bus. A neighbouring doctor, who saw him immediately after the accident, gave him 1/4 grain of morphine. When I saw him he was complaining of abdominal pain, and also the abdomen was generally rigid and tender. His pulse was 70, strong and steady, and the temperature 97° F. At operation I found much free blood, gas, and stomach contents in the abdominal cavity. These latter were swabbed out. The stomach was bruised and oedematous, and there was a rent about an inch long high up on the lesser curvature of the stomach, which was sutured, as in the previous case. The abdominal cavity was then filled with hot saline solution and the abdomen closed. The wound healed by first intention, and he was discharged to the convalescent home on December 31st.

Both these cases were caused by injuries when the stomach was full, and both were operated on within eight hours of the accident. In one case the upper part of the lesser curvature of the stomach was affected, and in the other the pyloric portion of the stomach. In neither case were there any other abdominal injuries, either internal or external. The immediate after-treatment was similar to that employed in the case of rupture of a gastric or duodenal ulcer.

I have examined both patients about four months after the injuries, and neither complains of any disability.

TOXIC JAUNDICE WITH ASCITES.

BY

ERNEST BULMER, M.D., M.R.C.P.ED., M.R.C.P.LOND.,

ASSISTANT PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM.

ALTHOUGH the occurrence of ascites in cases of toxic jaundice is a relatively uncommon happening, it is probable that its frequency is considerably greater than the very sparse literature would suggest. I have given much attention to certain aspects of liver disease, and naturally a fair concentration of liver cases has occurred in my practice; it was not until recently, however, that an example of the syndrome under consideration came under my care. A search of the literature disclosed only four references to it, and I felt that a brief review of the subject would not be devoid of interest.

Fiessinger and Brodin[1] and Fiessinger and Walter[2] give a very clear account of their conception of what they have termed the "syndrome ictéro-ascitique," and their description, both of the clinical features and of the pathology, cannot be bettered. During the course of a multilobular cirrhosis of the liver the clinical picture occasionally becomes dramatically altered by the sudden onset of ascites and jaundice. This jaundice, they say, is not the usual subicteric tint of the cirrhotic, but a frank icterus with deep coloration of the integuments, bile in the urine, and clay-coloured stools. Ascites develops rapidly, but the amount of the effusion, and the necessity for frequent tapping, vary widely in different cases. At the same time the patient's general condition degenerates rapidly, emaciation and marked weakness ensue, and there are usually digestive troubles; fever may appear, and its explanation is a matter of some difficulty.

The progress of the malady is variable; usually the condition is rapidly fatal, and the presence of the syndrome may be taken to mean the presence of an acute or subacute hepatitis—cholaemia may carry off the patient with its familiar train of symptoms. Some patients recover, however, and these are the ones in whom some definite cause can be found for the onset of toxic jaundice—the transitory toxaemia of surgical anaesthesia, the action of novarsenobillon, etc. Where no cause can be found the outlook is grave.

With regard to the pathology of the condition these authors describe a widespread fatty degeneration of the parenchymal cells of the liver, together with the usual findings of atrophic cirrhosis. Their explanation of the syndrome is ingenious; it is obvious that acute hepatitis in a normal liver would produce jaundice, and in such a liver the swelling of individual cells would result in an increase in the volume of the organ. If such a hepatitis arose in a cirrhotic liver jaundice would naturally ensue, but the fibrosis of the organ would prevent, in certain

cases, any increase in volume, and the swelling of the liver cells could only occur by encroachment on the portal capillaries with consequent portal obstruction. The work of Azoulay and Jaquelin[3] gives important confirmation to this contention. They found that the healthy human liver after death would increase and diminish in volume according to the pressure of the fluid with which it was perfused, but in a cirrhotic liver practically no volume changes could be produced.

Willcox[4] quotes two cases of an analogous but not exactly comparable type occurring as a result of tetrachlorethane poisoning; after many weeks of toxic jaundice symptoms of portal obstruction developed. There is, however, a definite probability that in these cases the obstruction was due to replacement fibrosis. There are, of course, other explanations, and the case quoted by Halita[5] of toxic jaundice of four months' duration with generalized anasarca cannot be accounted for on these lines. Halita regarded the dropsy as due to an upset in the metabolism of water, probably as the result of an alteration of the colloidal balance of the plasma.

The frequent oedema of the ankles in cases of pre-ascitic cirrhosis has been similarly ascribed. There is no reason why the two explanations should be mutually exclusive, as the two types of case are not clinically identical. A third explanation for the ascites is that it is caused by peritoneal irritation, and this cannot be denied; Fiessinger's views are, however, too alluring to be lightly spurned.

The case that came under my observation was that of a man aged 52; he was first seen in August, 1928, with the history that his Wassermann reaction two years before had been strongly positive and that he had then been *successfully treated with* novarsenobillon for paroxysmal tachycardia. The complaint had recurred, and a further course was suggested. Apart from rather an interesting tachycardia of the paroxysmal type there was nothing on examination, but the Wassermann reaction in the blood was strongly positive. He received six injections of 0.3 gram of novarsenobillon, a total of 1.8 grams, and his treatment was stopped on November 6th, as jaundice had developed. He was treated by his own doctor for some weeks, but as the jaundice did not clear up he was referred to me again on December 16th. He had a deep jaundice with bile in the urine and clay-coloured stools, and it appeared to be a case of rather severe toxic icterus. He was treated with the intravenous injection of sodium thiosulphate, and he received in all 4.5 grams. The jaundice increased rather than diminished, and the liver could be felt about two finger-breadths below the costal margin; ascites developed, and it became gross and of sufficient amount to produce oedema of the legs. He was sent back to his doctor on December 28th, and a very bad prognosis was given, with the suggestion that it must be a case of cancer of the liver, and the suggestion of toxic jaundice incorrect. He remained in bed for fifteen weeks, and both jaundice and ascites gradually cleared. He had become very emaciated, but it was now obvious that he was going to recover. On May 23rd I saw him again; he was rather thin, but there were no signs of jaundice; the liver appeared to be the same size as it had been at the height of the disease. Retrospectively the case was then diagnosed as an example of the ictero-ascitic syndrome, and it is difficult to see what else it could be. Liver function tests were carried out with the following results: Van den Bergh test negative. Icterus index 2. Levulose tolerance test: before levulose, blood sugar 0.093; half an hour after 50 grams, 0.154; 1 hour after, 0.168; 1½ hours after, 0.132; 2 hours after, 0.115; 2½ hours after, 0.108. Galactose tolerance test: before, 0.103; half an hour after 50 grams, 0.141; 1 hour after, 0.162; 1½ hours after, 0.110; 2 hours after, 0.105; 2½ hours after, 0.096.

It will be seen that both of the sugar tolerance tests show a definite abnormality in the functional capacity of the liver; this confirms my view of the pathology of the case—an initial cirrhosis of the liver, possibly of syphilitic origin, and a superimposed arsenical jaundice complicated by ascites.

Finally, due acknowledgement must be made to Mr. Garfield Thomas, biochemist to the General Hospital, for the chemical findings.

THE DICK TEST IN PREGNANCY.

REPORT ON 533 CASES IN THE OBSTETRICAL UNIT OF THE ROYAL FREE HOSPITAL.

BY

MARGARET SALMOND, M.D., B.S.LOND., M.R.C.S., L.R.C.P.,
SENIOR ASSISTANT, OBSTETRICAL AND GYNAECOLOGICAL UNIT;

AND

BEATRICE TURNER, F.R.C.S.ED., M.B., B.S.LOND., M.R.C.S., L.R.C.P.,
OBSTETRICAL AND GYNAECOLOGICAL REGISTRAR.

IN the *Lancet* (April 14th, 1928, pp. 746, 748) there were two interesting articles by Dr. Parish and Dr. Okell on the relationship of the haemolytic streptococci to scarlet fever and other diseases. The authors suggested that the closest relationship existed between the streptococci of puerperal fever and scarlet fever. It obviously became of great interest to see if there were any agreement between the reaction of pregnant women to the Dick test and their liability to puerperal sepsis. A paper by Burt-White[1] suggested that there was a definite relationship. The following investigation was also designed to test the hypothesis that such a relationship exists. Shortly after our work was begun the British Medical Association most generously awarded us a research grant, which has considerably facilitated the investigation.

In all, 533 cases have been tested. The test is performed as is described below on patients when they come into hospital in labour. Messrs. Burroughs Wellcome's standardized scarlet fever toxin and control are used. An intradermal injection of 0.2 c.cm. of toxin is made into the patient's left forearm, and 0.2 c.cm. of control into the right forearm.

The reactions are noted in six hours, and again in twelve to eighteen hours. Positive reactions begin to fade in about twenty-four hours. A positive reaction is indicated by an area of erythema, varying in size, surrounding the point of injection in the left forearm. Occasionally an erythematous area is also seen on the control arm. If there is an area of erythema only on the control arm a protein reaction is indicated, and this is also shown by areas of erythema of equal size on both arms. If there are erythematous areas on both, but that on the left is larger than that on the right, the reaction is positive. No erythema at all indicates a negative reaction. It is also of interest to note when doing the test whether the patient has previously had scarlet fever, erysipelas, puerperal fever, or severe sore throat.

The results of the tests are as follows, the Queen Charlotte's standard of morbidity (100° F. *on one occasion* at any time during the puerperium) having been used:

1. Of the 533 cases tested 158 (or 29.6 per cent.) were Dick-positive, 373 (or 69.9 per cent.) were Dick-negative, and 2 (or 0.3 per cent.) had protein reactions only.

2. Among the Dick-positive cases 126 (or 80 per cent.) remained afebrile throughout the puerperium, and 32 (or 20 per cent.) were at some time febrile, according to the above-named standard morbidity. Among the Dick-negative cases 317 (or 85 per cent.) remained afebrile, and 56 (or 15 per cent.) were febrile. In all, there were 443 (or 84 per cent.) afebrile patients, and 88 (or 16 per cent.) febrile patients.

3. An analysis of the afebrile and febrile cases in relation to complications yields the following statistical data: manipulations were necessary in the delivery of 50 Dick-positive patients and 140 Dick-negative patients; of the former, 14 (or 28 per cent.), and of the latter, 30 (or 21 per cent.) were febrile. Of the 108 remaining Dick-positive cases, in whose treatment manipulations were not undertaken, 18 (or 17 per cent.) were febrile; and of the corresponding 233 Dick-negative cases 26 (or 11 per cent.) were febrile. A history of previous attacks of scarlet fever, erysipelas, sore throat, etc., was obtained from 42 Dick-positive and from 123 Dick-negative cases. Of the former, 5 (or 12 per cent.), and of the latter, 22 (or 18 per cent.) were febrile. Among the 116 Dick-positive cases giving no such history 84 (or 72 per cent.) were febrile, and among

the 60 corresponding Dick-negative cases 34 (or 56 per cent.) were febrile.

The following are the clinical conditions that were found in association with the febrile cases: urinary infections with *B. coli* and streptococci isolated from catheter specimens; clinical sapraemia in conjunction with urinary infections; clinical sapraemia; streptococcal sore throat; breast abscess; white leg and clinical sapraemia and general peritonitis following septic abortion. There were three cases of Caesarean section in the series: one in which no cause for fever could be found, one with a septic abdominal wound, and one followed by general peritonitis. There was only one case of septicaemia in which the blood culture yielded *B. coli* and streptococci. In a number of cases in which a rise of temperature occurred on one occasion only no definite cause of fever could be found.

All the 32 febrile Dick-positive cases made a complete recovery; one death, from streptococcal general peritonitis following Caesarean section, occurred among the 56 febrile Dick-negative cases.

Discussion of Results.

The object of our work was to see if the pregnant woman giving a positive Dick reaction was more liable during the puerperium to suffer from "fever" than the negative reactor. Our results do not suggest that she is more liable. If she is, the difference is so small that it would obviously take a very large number of observations to establish it. Such a series of observations would have to be controlled by taking one or more cervical swabs in every case and examining them by complete bacteriological methods to establish the percentage incidence of haemolytic streptococci. It is not opportune to carry on the investigation on this large scale over a long period, and we have therefore been advised to discontinue the work.

The results obtained by Burt-White indicated a greater liability of the Dick-positive woman to suffer from "fever." We cannot give any explanation of the difference between those results and our own, and, as we are closing the research, we cannot further investigate the discrepancy.

Summary and Conclusions.

1. Of 533 pregnant women tested by the Dick method 70 per cent. were negative.

2. Of 158 Dick-positive reactors 20 per cent., and of 373 Dick-negative reactors 15 per cent., became febrile.

3. No attempt was made to decide whether the febrile condition was due to haemolytic streptococci or not.

4. There was *no significant* difference between the liability of the Dick-positive and Dick-negative pregnant women to suffer from "fever" in the puerperium.

We have to thank the British Medical Association for their grant, which has enabled us to do this work; Drs. O'Brien, Okell, and Parish for their help and advice, and Professor Dame Louise McIlroy for allowing us to publish the report of the cases from the Obstetrical Unit of the Royal Free Hospital.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

FULL-TERM ECTOPIC PREGNANCY.

THE following case is of interest on account of its comparative rarity.

Mrs. H., aged 22, was seen by one of us on April 25th, 1929. She complained of vomiting of greenish fluid, and looked extremely toxic. The temperature was normal, but the pulse rate was rapid (110). There was a history of amenorrhoea since June 6th, 1928, the menstrual flow on that occasion only lasting one day. She felt well, and pregnancy apparently was following a normal course until April 5th (about three weeks overdue, according to her reckoning). On this date she fell, striking the abdomen against a door. This was followed by severe abdominal pain, with vomiting, for two days, causing her to remain in bed. Since that date she had felt no foetal movements. She had had two normal confinements, two and three years ago respectively.

On examination the contour of the abdomen was found to be conical, with the apex at the umbilicus, and corresponded in size to a full-term pregnancy. The foetal parts were unusually palpable, even the individual skull bones could be felt and made to override one another. There were no foetal movements or heart sounds. Other systems were normal. Per vaginam the cervix was soft with the internal os closed, but the presenting part was too high to be palpated.

The patient was admitted to the Scarthoe Road Infirmary, where, owing to her toxic condition and the presumed death of the foetus, we decided to induce labour. Watson's method of induction was tried and failed. Three days later induction by the stomach-tube method was tried, but it was found that only about four inches of the tube could be introduced, giving rise to the suspicion of ectopic gestation.

An examination was then made under general anaesthesia, and it was found that the uterus, corresponding in size to a two months pregnancy, could be palpated against the right pelvic wall. A definite diagnosis of ectopic pregnancy was made. During examination a small piece of decidua was expelled and the remainder the following night.

On May 8th abdominal section was performed. On opening the peritoneal cavity *membranes presented. These were much thickened* (1/8 inch), greenish-brown in colour, and lightly adherent to the anterior abdominal wall. They were incised and a large quantity of greenish-brown fluid escaped. A macerated foetus of about 9 lb. weight was then removed.

Adhesions between the membranes and abdominal contents were now separated and in parts were found to be very firm. The structures of the broad ligament on the left side were directly continuous with the membranes and formed the entire placental attachment. The broad ligament was ligated and divided, the membranes, placenta, and a portion of the ligament being removed as a whole. The position and size of the uterus confirmed the findings at the previous examination. A large drainage tube was inserted into Douglas's pouch and the abdomen closed.

The convalescence of the patient was prolonged but without incident, and she left the infirmary six weeks after the operation.

In this case the relationship of the placenta to the broad ligament alone showed that the foetus must have escaped from the tube by a process of gradual erosion, an interesting point being that both the amnion and the chorion were intact.

We are indebted to the medical superintendent of the infirmary, Dr. S. W. Swindells, and to Dr. D. S. Campbell for their advice and permission to publish this case.

Grimsby.

PARAPHIMOSIS OF THE CLITORIS.

I WAS greatly interested in Mr. R. J. Willan's description of a case of paraphimosis of the clitoris, which appeared in the issue of the *British Medical Journal* on December 22nd, 1928 (p. 1130). This condition is evidently a rare one, so that a case of mine in a girl, aged 9 years, may be worth recording.

This child was out walking with her guardian when it was noticed that she was limping and appeared to be suffering some pain. When questioned by the guardian her reply was evasive, but she gave the information that two days previously she had fallen when climbing a fence and had injured herself. The guardian became alarmed when she discovered the site of the trouble, and decided to have her examined at once by a doctor.

When I saw the child on January 22nd, 1929, there was a large abrasion upon the outer aspect of the right thigh, and this seemed to confirm the history of a fall. I then placed the child in the lithotomy position and examined the external genitals in a bright light. I was surprised to find what I took to be a condition of paraphimosis of the clitoris. On closer inspection, after cleaning the parts with hydrogen peroxide and saline, I made an endeavour to identify the disturbed anatomical relations. At the base of the swollen and oedematous clitoris was a band of constriction and ulceration. From the dorsal aspect of this constriction a tiny speck of foreign matter was seen. I seized this with a pair of epilating forceps, and for some queer reason put into action the mechanism for taking out a suture. Sure enough, a short strand of linen thread tied tightly in a knot came away with a snip of the scissors.

On displaying this before the patient's eyes and asking her what she knew of it, a confession was finally wrung from her that, with the assistance of a girl friend, a piece of sewing machine thread had been deliberately tied round the organ, but their efforts to remove the string had been unsuccessful. Hence the awkward situation.

I must state in conclusion that I strongly suspect that the cause of the condition in Mr. Willan's case was not altogether an accidental one.

Reviews.

ULTRA-MICROSCOPIC VIRUSES.

THE literature of the medical sciences has assumed such enormous proportions, the advance in knowledge is so rapid and specialization so highly developed, that the writing of a treatise on any but the most circumscribed subject is beyond the powers of a single individual. Even a branch of bacteriology, such as the ultra-microscopic viruses, cannot receive adequate and rapid treatment from a single pen, so extensive has its literature become. Dr. HAUDUROY is aware of this difficulty, for in the introduction to *Les Ultravirus et les Formes Filtrantes des Microbes*[1] he warns the reader against expecting anything in the nature of a treatise, but it is to be feared that he has allowed enthusiasm for his subject to overcome his better judgement. He has attempted to cover too large a field in a too limited space and time, with the inevitable result of sketchy and inadequate treatment.

The book is divided into two parts, the first dealing with the ultra-microscopic viruses, and the second devoted to a consideration of the question of filterable forms of bacteria. The former commences with what purports to be a summary of our knowledge of the various diseases caused by ultra-microscopic viruses, followed by chapters on the principal characters of these viruses, their physiology, cultivation, the histology of virus diseases, immunity, and epidemiology. While making all allowances for defects inherent in such brevity of exposition, it must really be questioned whether, in many instances, the author does give a correct representation of the present position of our knowledge. Who, for instance, would be prepared to accept, as reflecting our present knowledge of the bacteriophage, an account in which this agent is treated dogmatically as a bacterial parasite without any mention of alternative hypotheses? Dr. Hauduroy may be right in his opinion on this question, but there are equally competent observers who do not share this view. Again, the section devoted to epidemic encephalitis in man is entirely coloured by the work of Levaditi and his collaborators, to the exclusion of conflicting results obtained by other investigators. Brevity has had other unfortunate consequences. Not infrequently the bald statement of fact, even though true, is deprived of its value for want of a few all-important details. For instance, of what use is it to say that a virus is destroyed by ultra-violet light, or that it is not susceptible to centrifugalization? Such information is valueless when shorn of the experimental details. In the introduction the author tells us that, contrary to the generally held opinion, these viruses can be quite readily cultivated by means of a rather special technique. It is true that he says that this is done daily in the laboratory; nevertheless, one turns hopefully to the chapter on cultivation only to find the statement that when a susceptible animal is inoculated with a virus, and more virus is recovered from the lesions so produced, cultivation in vitro has been realized. But surely it is only the ultra-philosophic individual who ever expressed a contrary opinion; most virus workers have long held this "revolutionary" view. This part of the book is practically without bibliography, and the author seems unaware of much work of outstanding merit published in languages other than French. Where foreign literature is quoted the reference is sometimes incorrect. Findlay, for instance, cultivated the virus of fowl-pox, not fowl-plague, and the excellent American work on the transmission of dengue was carried out by Siler, Hall, and Hitchens, not Giler and Halls.

In the second part of the volume dealing with the filterable forms of bacteria the author speaks with authority, for he has devoted the major part of the last few years to a study of this problem. It is not surprising that this conception, upsetting as it is to orthodox bacteriology, should have been received with scepticism and antagonism. The contention that visible bacteria have a filterable phase is supported to-day, however, by such a wealth of testimony from independent sources that it can no longer be cast lightly aside; it demands serious consideration. The author describes how these filterable forms can be obtained and the technique necessary for their cultivation and transformation into the visible bacterial phase. Finally, he discusses their possible role in pathology. Whatever views one may hold, this part of the book will provide stimulating reading.

THE CRITICAL AGE.

The Critical Age[2] is a translation of the second Spanish edition of a work on the climacteric by GREGORIO MARAÑÓN, professor of medical pathology at Madrid. It is edited and annotated by Professor CAREY CULBERTSON of Chicago, and is in many ways remarkable, more especially in the fresh aspect from which the subject is regarded. Professor Marañón disclaims the narrow perspective of the gynaecologist and claims to have considered the subject from the general practitioner's point of view, by which is meant that of general medicine. The term "critical age" is preferred and justified by the consideration given to this epoch in the life of both sexes. It is defined as "a necessary phenomenon in the evolution of every human being who reaches old age, be it man or woman." Frequent reference is made throughout to conditions met with in the male, and a whole chapter is specially devoted to the critical age in man, particularly in reference to its emotional disorders. The two are compared; the masculine episode comes later, is of more diffuse evolution and limits, and its organic symptomatology more attenuated. The menopause is strictly differentiated from the climacteric, the former being regarded merely as a genital symptom marking the cessation of the reproductive function.

The first few chapters are given up to a discussion of the endocrine elements, in order to show that the disorders associated with this epoch in life are not due to insufficiency of the genital gland, but are rather the expression of a complex endocrine crisis, that differs in every case, because any or all systems of the body may play a part in it and in variable degree. The nervous and circulatory systems are most constantly affected, the respiratory and digestive less often, but the primary cause is the same in all, the reaction of the nervous and endocrine-vegetative systems to the gonadal insufficiency. The true climacteric symptoms are endocrine-vegetative, and the various glandular and nervous upsets of which they are the expression form the principal theme of the book. Symptoms arising from disordered function in the circulatory, nervous, sensory and psychic, endocrine, and digestive systems are discussed in the middle chapters, the artificial menopause, the critical age in the male, and treatment occupying the last four chapters.

In a nutshell the thesis of the author is that pathologically and clinically the critical age is characterized by instability. The emotional disturbances of this period being specially significant, considerable space is devoted to the full discussion of the nature and treatment of emotional disorder, and, in this connexion, the writer's enthusiasm over the results obtained by ovarian therapy will surprise most gynaecologists in this country. He advises beginning treatment as soon as symptoms appear and continuing it, in association with such other medical treatment (for example, circulatory tonics, sedatives) as may be indicated by the nature of the symptoms, till they have all disappeared. He prefers the use of desiccated whole-gland preparations, given by the mouth, and gives instructions for the selection of cases calling for the administration of thyroid and other gland extracts, and regarding diet and general management.

The book can be recommended as an interesting and useful contribution to a difficult subject, but the reader must be critical and not carried away by the author's obvious enthusiasm for his own views.

[2] *The Climacteric (The Critical Age).* By Gregorio Marañón. Translated by K. S. Stevens. Edited by Carey Culbertson, A.B., M.D., F.A.C.S. London: H. Kimpton. 1929. (6 × 9½, pp. 425; 18 figures; 1 plate. 28s. net.)

"KER'S INFECTIOUS DISEASES."

THE third edition of *Ker's Infectious Diseases*[3] has been revised by Dr. CLAUDE RUNDLE, who was also responsible for the revision of the smaller manual of fevers, to which we drew attention in the *Journal* of August 20th, 1927. As nine years have elapsed since the appearance of the second edition of the larger work numerous important additions had to be made, particularly in the chapters on scarlet fever, diphtheria, and measles. The present edition differs externally from its predecessors in being of a smaller and more convenient size. Its price also is lower, and we venture to think it might have been reduced still further by the omission of several worthless plates, supposed to represent the eruption of rubella (p. 72), scarlet fever (p. 96), and serum sickness (pp. 434 and 438) respectively.

Dr. Rundle has done his work well on the whole, but a few points call for criticism. We think it unfortunate that in the opening sentence of his preface, in which he says that "important results have been attained during the past few years by workers in immunology both in the United States and in this country," he should not have included Continental workers. In view of the fact, ascertained by the comparative observations of Pospischill and Weiss many years ago, that the character of the diet does not have any influence on the occurrence of nephritis, we regard the withholding of meat diet till the middle of the fourth week as an unnecessary restriction. Moreover, the exclusive milk diet recommended for nephritis cases on page 140 is not in accordance with modern practice. The same may be said of the routine administration of alcohol in diphtheria in all but the mildest cases (p. 444), while the use of "alcoholic stimulants" such as port wine or stout for small-pox convalescents (p. 189) is becoming an obsolete practice. Lastly, in view of the increasing importance which the history of medicine is assuming in the medical curriculum, the absence of even the briefest historical introduction to the various diseases in a work of this size is to be regretted. These, however, are comparatively minor criticisms of a work that has justly won a high reputation.

PRACTICAL SURGERY OF THE ABDOMEN.

Practical Surgery of the Abdomen,[4] by Dr. GEORGE H. JUILLY of San Francisco, differs little in aim and method from many of the textbooks lately produced in this country. The author presents the subject in a practical manner, laying special stress on diagnosis, and describing for each condition the operation he has found best in his own practice. In addressing his readers in the second person, he conveys the impression of a general marshalling his forces and setting them to their allotted tasks. The work is in two volumes, and the author has made use of the method increasingly popular in present-day surgical textbooks of illustrating, with a profusion of pen-and-ink sketches, the anatomy and successive stages of the operations he describes. In the first volume he deals with surface anatomy, the diagnosis of abdominal diseases, laparotomy, and the operations on the alimentary tract, biliary tract, liver, pancreas, and spleen. In the second he deals with the genito-urinary tract, acute lesions of the abdomen, gynaecology and obstetrics, abdominal surgery of the diabetic subject, anaesthesia, and post-operative care. In discussing gastric and duodenal ulcers he holds, contrary to the general view, that all chronic ulcers should be treated by operation. Gastric ulcers, he believes, should be excised, and, if there is a six-hour residue, posterior gastro-enterostomy should be performed as well. He advocates pylorectomy for large ulcers and carcinoma only. Where the patient's symptoms and the radiological appearances suggest duodenal ulcer, he recommends gastro-enterostomy, even if the ulcer is not seen at operation. Jejunal ulcers, in his view, follow when the stoma is made too large. We cannot agree that any of the procedures he describes for removing a safety-pin from the stomach, though they are in accord with those generally given in the textbooks, can compare in simplicity with that of passing a rubber stomach tube, threading and clipping on to it the pin, and then withdrawing the tube with the pin attached. The work includes no account of treatment by radium, but otherwise covers practically the whole of modern operative technique. Its style is colloquial, dogmatic, and terse; its production is admirable.

THE ART OF THE APOTHECARY.

IN *The Mystery and Art of the Apothecary*[5] Mr. C. J. S. THOMPSON, formerly in charge of the Wellcome Historical Museum and now Honorary Curator of the Historical Section of the Museum of the Royal College of Surgeons of England, adds another to the interesting books he has written on those by-paths of medical history about which he has such an extensive store of curious knowledge. The present well-illustrated volume is full of out-of-the-way information, and in a charmingly easy style traces the history of the dispensers of drugs from Babylonian and Assyrian times up to the end of the eighteenth century. Among the ancient Greeks there were two distinct classes, the rhizotomists who collected the roots and herbs and prepared the preparations, and the pharmacopolists who sold them in the public market places. The word apothecary, first employed by the Romans, was derived from apotheca, meaning a store-room. In a chapter on the oldest remedies in the world, the three ancient Greek preparations—holy bitter (hiera picra), sacred sealed earth from the island of Lemnos, and theriaca or treacle—are described at some length, and the variations in their formulae set out; the name treacle, for example, was applied to any thick compound of which honey was the chief ingredient. Among the numerous antidotes employed in classical days, some were associated with the names of famous persons, such as the "antidote of Caesar," or the "gold antidote," which contained forty ingredients, including gold and silver, and took a year to make.

During the eighth to the twelfth century pharmacy advanced among the Arabians, and the practice of the apothecary and the physician were distinct; the Mohammedan invasion of Western Europe carried the study of drugs into Spain and founded universities before the twelfth century. The earliest record of the apothecary in England is in 1180, and the account of the relations, in the succeeding centuries, of the apothecaries with the City Guilds—the Pepperers, the Spicers, and the Grocers—throws light on the slow progress of the healing art. The story of the pharmacopoeias dates from the early days of printing, when in 1498 a small folio of 88 leaves appeared at Florence, where "the learned doctors of medicine of the College of Florence, in order to prevent errors and to preserve constancy in the preparations employed in their practice, sought to collect the most important formulae from the works of Mesue, Nicholas, Avicenna, Galen, and other authors."

The history of the Society of Apothecaries of London and of some famous drugs is attractively sketched, and the story of the long disputes between the physicians and apothecaries, satirized by Garth in his well-known poem, *The Dispensary*, published anonymously in 1699, carries the reader towards more modern days. Mr. Thompson is to be congratulated on the enormous amount of information which he has collected and presented in an eminently readable form.

NOTES ON BOOKS.

A FOURTH edition of BOURNE'S *Synopsis of Midwifery and Gynaecology*[6] has now appeared. The work has been fully revised, and every effort has been made to render it as practically useful as possible to the medical student and general practitioner. It makes no pretence at being a textbook, and is arranged simply as a manual for reference or for revision

[5] *The Mystery and Art of the Apothecary.* By C. J. S. Thompson, M.B.E. London: John Lane, The Bodley Head, Ltd. 1929. (Demy 8vo, pp. viii + 287; 28 illustrations. 12s. 6d. net.)

before an examination. As such its popularity has been well deserved, and the present edition is a worthy successor to earlier ones.

The lectures on certain medical subjects given under the aegis of the Medical School of Harvard serve a very useful purpose in health propaganda; some of these—for example, on cancer and pneumonia—have been published, and now, in *The Facts of Modern Medicine*,[7] Dr. F. W. PALFREY, who is an instructor in medicine and in hygiene in that university, has provided *A Simplified Statement of Established Knowledge on Medical Subjects, with Reference also to certain Current Misconceptions*. The last part of the subtitle may perhaps recall the books on vulgar medical errors in the seventeenth century, by James Primrose, James Thompson, and Obadiah Walker. Some books of this kind are of good report, and Dr. Palfrey's is written on sound lines. It expands the scope of the public lectures given by the Medical School of Harvard, and provides the amount of knowledge which every cultivated layman should have of human physiology, normal and disordered, in clear and pleasantly written chapters.

Mr. PICKLES'S *Practical Chemistry for Senior Forms*[8] is intended for the use of students following an advanced science course and taking higher schools examinations. The book contains directions for the performance of about 130 experiments in inorganic chemistry, physical chemistry, and organic chemistry; methods are also given for preparing a number of organic compounds, and there is a short account of the methods of gas analysis by Mr. Brewin. The text is clearly written, and the chemical exercises it contains seem to be well fitted for the students for whom the book has been written, and to them it may be warmly commended.

The Physics of X-Ray Therapy,[9] by W. V. MAYNEORD, is a book which should be of use to students and radiologists, especially those who practise *x*-ray therapy. The most important section is that devoted to the consideration of practical therapeutic *x*-ray measurement, in which all the different methods are described and illustrated. Other sections deal with the radiation from an *x*-ray tube, *x* rays and matter, *x*-ray absorption, and *x*-ray apparatus. The book is well written, easily understood, and excellently illustrated.

To the many medical students whose previous studies have not taken them far into the Latin language Mr. TREASE'S *Aids to Pharmaceutical Latin*[10] should come as a boon and a blessing. The author set out with the intention of providing pharmaceutical and medical students with a concise Latin Grammar adapted to their special needs, and he seems to have succeeded in his endeavour. The book is clearly written, and covers the ground in a satisfactory manner. A few misprints may be noted: on page 96 *decubita* should be *decubitus*; on page 99 *exsiccatae* should be *exsiccati*; on page 100, ten lines from the bottom, *Lavandutae* should be *Lavandulae*.

The second edition, revised, of *Lippincott's Pocket Formulary*,[11] by Dr. GEORGE E. REHBERGER, contains additions to the description and treatment of several diseases. Under the alphabetical headings of each condition several prescriptions are given, together with a brief account of the dietetic and general measures suitable to the case. The second part of the book gives lists of the drugs and preparations of the *U.S.P.X*; of the medical preparations of the United States National Formulary; and of new and unofficial remedies. Various weights, measures, and tables are appended to the little volume. *The New Pocket Medical Formulary*,[12] by Dr W. E. FITCH, is another American aid to prescribing, which has reached its fifth edition. Whether it has been revised seems doubtful, judging from Dr. Fitch's remarks about the use of organic salts of arsenic in syphilis. To the majority of practitioners these remarks will probably appear decidedly archaic. Extensive diet lists are appended to the book, together with tables of differential diagnosis. A useful feature for a polyglot country is a new section entitled the "physician's interpreter," wherein a series of questions designed to assist diagnosis are given in English, French, Italian, and German. An English effort at compiling formulae for various diseases is Dr. ESPINE WARD'S *Favourite Prescriptions*,[13] now in its second edition. Unlike Dr. Rehberger, who gives an elaborate account of various courses of arsenic compounds for two years in the treatment of syphilis, and unlike Dr. Fitch, who mentions salvarsan, but states that its use is "confined to certain investigators," Dr. Ward contents himself with giving prescriptions for sundry mercury pills, mixtures, ointments, and washes for the treatment of this disease. A useful feature in his book is the interleaving, whereby space is provided for accumulating other prescriptions. Hints for the treatment of cases of poisoning are also given.

The last two volumes of the Notable British Trials Series deal respectively with the case of John Donald Merrett,[14] who was tried in Edinburgh, in February, 1927, for the murder of his mother, and with that of Jean Pierre Vaquier,[15] who was tried at Guildford, in April, 1924, and found guilty of the murder of Alfred Jones, licensee of the Blue Anchor Hotel at Byfleet. Each volume is carefully edited and well produced, and in each the full report of the trial is preceded by an informative introductory note. Merrett's trial must have been one of the last appearances of Professor Harvey Littlejohn in the witness-box; the other medical witnesses included Professor Glaister, Professor George M. Robertson, and Sir Bernard Spilsbury.

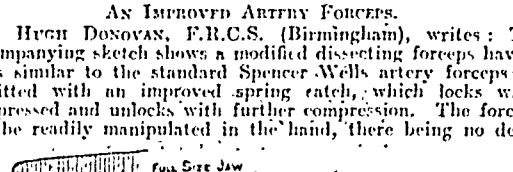
PREPARATIONS AND APPLIANCES.

AN IMPROVED ARTERY FORCEPS.

MR. HUGH DONOVAN, F.R.C.S. (Birmingham), writes: The accompanying sketch shows a modified dissecting forceps having jaws similar to the standard Spencer Wells artery forceps; it is fitted with an improved spring catch, which locks when compressed and unlocks with further compression. The forceps can be readily manipulated in the hand, there being no delay



in inserting digits into rings as in ordinary forceps, and it can be gently and easily removed with either hand, even by an unpractised assistant. The instrument has been made to my design by Messrs. Allen and Hanburys, Ltd., Wigmore Street, W.1.

AN ORGANIC GOLD SALT.

Allochrysine Lumiere (sodium auro-proposal sulphonate) contains 35 per cent. of its weight in gold. It is supplied in ampoules for intramuscular or subcutaneous injection. Each ampoule contains 0.2 gram of the salt, which is injected in a bulk of 10 c.cm. of saline. According to the makers this compound represents a considerable advance on sanocrysin (double thiosulphate of gold and sodium). The advantages claimed are that it produces no local or general reaction, it does not produce albuminuria, and its toxicity is very feeble. Clinical tests are said to have given favourable results in tuberculosis of various forms. The general claim made on behalf of this new gold compound is that it deserves attention by investigators of the therapeutics of tuberculosis. The distributing agents are the Anglo-French Drug Company, Ltd.

SICCOPAN.

"Siccopan" is a preparation containing haemoglobin, albumin, lecithin, calcium lactate, and soluble silicic acid. It is recommended as a tonic food in anaemia and conditions of undernutrition. The claims for the food are supported by an article from Professor Zuelzer's clinic by Dr. Fritz Stern. The author has used the preparation with benefit in a variety of diseases, and its use has been followed by an increase in the haemoglobin content of the blood. He points out, however, that the absorption of the haemoglobin is not complete. The distributors of this product in Great Britain are Messrs. Coates and Cooper, Great Tower Street, E.C.3.

BULBOCAPNINE.

Messrs. Burroughs Wellcome and Co. now manufacture tabloid hypodermic bulbocapnine phosphate 0.1 gram. Bulbocapnine was formerly used in the treatment of tremor due to paralysis agitans; this preparation is recommended for the treatment of disorders of behaviour in chronic epidemic encephalitis in children.

Bulbocapnine is obtainable also, in tablets and ampoules, from Messrs. H. R. Napp, Ltd.

A NEW DENTIFRICE.

Genozo tooth paste, prepared by Messrs. Genatosan, Ltd., represents an interesting application of Besredka's methods of producing local immunity. The special point about the preparation is that it contains an er[illegible] emulsion to the gums that produce pyorrhoea. It is hoped that [illegible] will confer local

British Medical Journal.

SATURDAY, JULY 27TH, 1929.

THE PRESIDENT'S ADDRESS.

AMONG the resolutions passed at the original foundation meeting of the Provincial Medical and Surgical Association in 1832 was one which referred to the Annual Meeting: "At this meeting it is proposed that one of the members shall be appointed to give, at the *next Annual Meeting, an account of the state of* progress of medical science during the last year, or an oration on some subject connected with medical science, or a biographical memoir of some eminent cultivator of medical science who may have resided in the Provinces." This "retrospective address," as it came to be called, although in the early years it was not invariably delivered by the President, is the direct ancestor of the Presidential Address which has since been delivered annually. It is often profitable to look back and see what our distinguished forerunners did, and some such intention was no doubt in Professor A. H. Burgess's mind when he set to work to prepare his Presidential Address to the British Medical Association, of which the full text appears in our opening pages to-day.

Ninety-three years have passed since the Provincial Medical and Surgical Association first met in Manchester. It was the fourth anniversary of the Association's foundation, and Mr. John Green Crosse, F.R.S., surgeon to the Norfolk and Norwich Hospital, delivered the retrospective address. Although he had only to review the progress of medicine and surgery during one year, the orator professed to find himself overwhelmed by the magnitude of the task. "In a yearly retrospect of medicine and its associate sciences," he said, "so much new matter presents itself, so many changes and improvements have been effected, that the mind of an individual unaccustomed to the task feels oppressed by its immensity, and if not bound by the sacredness of a pledge, would thankfully relinquish it to abler capacities." Mr. Crosse, who no doubt did not intend his apology to be taken quite literally, then went on to comment on a great variety of subjects, the first of which was the rise and progress of provincial medical schools, and in particular the "Plan of a University for the Town of Manchester by H. L. Jones, M.A." If the President of 1836 really felt his task a heavy one, what, we may ask, would he have thought of that undertaken by the President of 1929, who led his hearers back to the time when Lister had evolved and was perfecting the antiseptic treatment of wounds? For although the title of Professor Burgess's Address is "The debt of modern surgery to the ancillary sciences," any consideration of that subject necessarily involves a great deal of retrospective study of medicine and surgery. The fact that on physiology are based, not only our present knowledge, but all prospect of advance in medicine, might seem too self-evident to require mention to a medical audience. But public addresses of this nature, delivered in a great centre such as Manchester, are reported far and wide in the lay newspapers, and it is well that their readers should know how unanimous the medical profession is in the belief that in experimental physiology lies one of our greatest hopes of progress in medical treatment. By a happy coincidence this fundamental idea is developed also by Professor W. E. Dixon in his presidential address to the Section of Physiology of the British Association at Capetown, as will be seen from the abridged version printed elsewhere in this issue.

It was on the science of bacteriology as practised by Pasteur that Lister based his work. Chemistry had long before supplied us with effective anaesthetics, and it was on the science of electro-physics and the work of Crookes, and others not in our profession, that Röntgen's happy discovery was based. Radium, a more recent gift, was revealed by the industry of two scientific workers who were not looking for therapeutic substances or procedures. These discoveries stand out from all others, perhaps on account of the dramatic suddenness with which they brought about advances in surgical practice, but, as Professor Burgess reminds us, surgical thought and practice have been influenced, directly and indirectly, by every discovery that has been made in natural science. Progress is attained not only by sudden steps, but also by slopes, which may be so gentle that their gradient escapes observation and estimation. To go beyond the somewhat narrow confines of surgery into the realm of general medicine, who can estimate what our profession, indeed, what all mankind, owes to the once-despised science of entomology, that "bug-hunting" without which malaria and other insect-borne diseases might never have been successfully grappled with?

The great part played by Edward Lund in the introduction of the antiseptic system to Manchester is worthy of remembrance. This original-minded surgeon rendered valuable services to surgery in general and to orthopaedic surgery in particular, and the fact that he had to provide his own antiseptic dressings indicates how grave were the obstacles sometimes put in the way of a progressive surgeon, even in so liberal and enlightened a city as Manchester. The substitution of aseptic for antiseptic procedure occurred later in the country of Lister's birth than in some parts of the Continent, but we welcome the President's reminder that the principle of both methods is the same—namely, the exclusion of pathogenic organisms from wounds. The experiences of the great war forced us, in the presence of wounds already gravely infected, once more to fall back on antiseptic measures, for in principle there is no difference between Lister's carbolic solution and the bipp of Rutherford Morison or the solutions of Carrel and Dakin. It is well, too, that we should be reminded not only of the extension of the field of surgery—what one may call its qualitative advances—but of its quantitative increase also. A hundred years ago, about the time that Mr. Crosse was delivering his retrospective address, there was a week during which, according to the press, there were no operations in the theatres of the hospitals of London. When by contrast we consider the statistics quoted by Professor Burgess we may faintly apprehend what vast Aceldamas of suffering remained unrelieved before the days of anaesthetics and antiseptics, and feel assured that those who come after us will be able to relieve much suffering and disability before which even the surgery of 1929 is helpless.

Probably no new method of treatment has been more quickly popularized than actinotherapy. The public, especially the public of these cloud-shaded islands, has readily assimilated the idea of the beneficial effects of sunlight in all sorts of diseases, and, believing that one cannot have too much of a good thing, is inclined to expect too much of ultra-violet ray apparatus. To many persons it does not seem to have occurred that on the hypothesis of the all-healing but

wholly innocuous power of sunshine those races who have had so much of it ought to have outstripped the Nordic races in energy and ability, and the Goths and Northmen ought not to have overrun Europe from Britain to Constantinople and the Pillars of Hercules. The President did well to warn his hearers, and those who read reports of his address, that, like most powerful remedies, ultra-violet rays are two-edged weapons, capable, if improperly used, of causing much harm. There is a therapeutic dose and a poisonous dose of the rays, just as there is of hydrocyanic acid or arsenic, and only the expert can decide on the appropriate amount to administer in any given circumstances. Professor Burgess's list of conditions in which the rays should not be used is a formidable one. The same cautions apply, as he says, to other powerful remedies, such as applications of the various kinds of electric current. The action of the British Medical Association and the Society of Apothecaries of London should lead to a great improvement in present conditions by enabling the public to know who is and who is not qualified to administer actinotherapy

Readers of this address may profitably digest the President's remarks on the progress of treatment of rickets, and on the importance of recent inquiries into the assessment of renal function which have a direct bearing on the prognosis of cases of prostatectomy. All of us will join with him in the aspiration that, strivers after the ever-receding goal of perfection, we may be animated by the motto of Manchester University and continue to seek the very highest.

THE NEGLECT OF PHARMACOLOGY.

PROFESSOR W. E. DIXON, in his presidential address to the Section of Physiology of the British Association, of which a full abstract appears this week at page 138, has made an admirable summary of recent progress in the sciences of pharmacology and therapeutics—above all, in their chemotherapeutic and endocrinological aspects. In surveying the field covered by this paper one cannot but realize that, while British workers have contributed largely to the development of endocrinology, their contribution to chemotherapy has been relatively small. The explanation of this anomaly lies perhaps in the widely different attitudes taken up in this country towards the study of physiology and of pharmacology respectively. The former has been consistently fostered; the latter is consistently neglected. We have in England and Scotland numerous strong schools of physiology, to whose work Professor Dixon pays a just tribute; these schools have not only played an outstanding part in the development of endocrinology, but have been pioneers in the study of vitamins—another aspect of physiology which is attaining increasing importance in therapeutics. But full-time teachers of pharmacology in this country are few, and still fewer are full-time chairs in the subject at the universities. It is little matter for surprise, therefore, that in chemotherapy—a subject which is bound up with pharmacology, but receives only little help from pure physiology—the British contribution has been inadequate.

The relative neglect of pharmacology in this country is the more to be deplored in view of the fact that, as Professor Dixon so clearly shows, much of the recent advance in chemotherapy has concerned itself with the quest of specific remedies for tropical diseases—a matter of more direct interest to this country than to any other. Life in the tropics, particularly in tropical Africa, depends upon the possession of adequate means for the prevention and cure of protozoal diseases; it is unsatisfactory, humiliating even, that we should be dependent on workers of other countries—on, for example, the Americans, Frenchmen, and Germans, who synthesized tryparsamide, stovarsol, Bayer 205, and plasmoquine (to name but a few of the more important products)—for the discovery of remedies which are vital to the well-being of large populations within our own Empire. To know the cause of an evil is by no means the same as to find its cure; but in this matter the diagnosis sufficiently suggests the proper treatment. "No branch of experimental biology," says Professor Dixon, "has received less consideration in Great Britain than that of pharmacology; it is also the most neglected branch of medicine, and, although the object of medicine is the healing of the sick, it is amazing that medical schools in Britain, often equipped with all other modern laboratories, lack departments of therapeutics." And later he says: "Britain for fifty years has every reason to be proud of her progress and achievements in physiology; it is acknowledged that she can show records second to none, and that her savants have included some of the world's greatest investigators. It remains for us to hope that in the future she may attain equal success in the associated sciences directly concerned with the relief of suffering and cure of disease."

Professor Dixon has rendered valuable service to medical education in Great Britain by focusing attention on one of its outstanding defects. The systematic search for synthetic drugs promises in the future to yield even more important results than it has in the past two decades. If our country is to enter this field of investigation with a sufficient equipment it will need strong schools of pharmacology, in each of which whole-time specialists may work together as a team. Until such provision has been made there is a danger that chemotherapy in Great Britain will remain to a large extent parasitic on ideas and discoveries imported from abroad.

ANNUAL MEETING NOTES.

"The Book of Manchester."

ANNUAL Meetings come and go, and memories fade all too soon. It is therefore very appropriate that such a souvenir volume as *The Book of Manchester and Salford*[1] should have been prepared, and that each member who is attending the present meeting, which is now drawing to its close, should have a permanent record of the place where he has spent happy and profitable hours. In the compilation of this book the Printing and Publicity Committee, of which Dr. E. M. Brockbank was the chairman and guiding spirit, had no easy task, but it was able to enlist support from many sources, and has produced a really interesting account of the various aspects of the life and growth of a great city, particular attention being paid, naturally, to the local medical institutions, municipal developments, commercial achievements, and the evolution of the University. Mr. Ernest Axon, who is deputy chief librarian of the Manchester public libraries, gives a readable account of the general and political history of Manchester, which is followed appropriately by a description of the city as it is to-day by Mr. Henry Price, the city architect. Dr. E. M. Brockbank—to whom our readers have been indebted for the five graphic articles on Manchester published on

[1] *The Book of Manchester and Salford.* Written for the Ninety-seventh Annual Meeting of the British Medical Association in July, 1929. Manchester: G. Falkner and Sons, Ltd. (10s. 6d.)

December 1st, 1928, and January 26th, April 27th, June 8th, and July 13th, 1929—deals here in fuller detail with the history of collegiate teaching in the city, and the progress of the local hospitals. A particularly interesting section of this chapter is Dr. Brockbank's series of biographical notes on pioneers in medical teaching. Mr. Edward Fiddes, the Ward professor of history, supplies a brief but illuminating account of the growth of the Victoria University of Manchester, which was the first of the provincial universities founded in the later nineteenth and earlier twentieth centuries, and has had a considerable influence in determining the character of later foundations of this kind. Short descriptions are also given of various other educational institutions in the city. Lieut.-Colonel G. Westcott, Lord Mayor of Manchester, in a practical delineation of the work of the corporation as regards local government and development, calls attention to the effective way in which street and house refuse is being utilized for such purposes as land reclamation and the manufacture of concentrated manure, soap, tallow, and mortar. The activities of Salford are ably portrayed by Councillor A. H. Collins, the Mayor of this essentially industrial city. The pioneer work of Manchester and Salford as regards the playing fields movement—on which a note is contributed by Councillor Will Melland—may be singled out for praise in view of the fact that the Manchester and Salford Playing Fields Society was founded so long ago as 1907, and has therefore attained its majority in a campaign with which medical practitioners must feel special sympathy. Articles relating to industry and commerce could not be absent from any attempt to estimate the part played in the present day by Manchester, and members of the Association are here given authoritative information about the Ship Canal, the Chamber of Commerce, and the Lancashire cotton trade. Manchester has a well-deserved reputation for music and art, and the short notes on this topic will be welcomed. Professor Bragg contributes an article on the Literary and Philosophical Society, and Dr. Brockbank on the Manchester Medical Society, with its valuable library. It is impossible to comment on every detail in this praiseworthy addition to the long series of books which have been prepared for visitors to the Annual Meetings, but a special word of commendation may perhaps be allowed for the excellent illustrations. Hearty congratulations must be accorded to Dr. Brockbank and his committee for their share in securing that the Annual Meeting of 1929 shall not soon be forgotten.

The Annual Representative Meeting.

Friday, July 19th.

BEFORE settling to the more arduous business of the day, the Representative Body carried by acclamation the election of Sir Robert Philip as Vice-President of the Association. It had also to record its appreciation of two generous gifts —that of a symbolic staff of the Association from Mr. Bishop Harman, and that of a Past-President's badge from the President, Sir Ewen Maclean. The meeting was also distinguished by the presence, with the President-Elect, Professor Burgess, of the President nominated for 1930, Professor Harvey Smith of Winnipeg, who received a warm welcome. Nothing could have been better of its kind than Dr. Hawthorne's speech in acknowledgement of the civic welcome by the Lord Mayor of Manchester.

The greater part of the first day's session was devoted to a detailed discussion of the revised and expanded statement of hospital policy elaborated by the Hospitals Committee during the past twelve months. The character of the discussion marks a definite stage in the progress of the Association policy towards general acceptance by the profession; although, as Sir Richard Luce pointed out, that policy is still to be regarded as educative rather than mandatory. Hitherto controversy has centred upon the basic principles underlying the policy. On Friday attention was in the main focused upon the best methods of its immediate application in a period of rapid transition. Last year the Representative Body directed the formulation of a middle-class hospital policy. This year it was content to accept the finding of the Council that its existing policy was comprehensive enough to be adapted to this field of hospital development, as well as to those for which it was originally formulated. The substantial acceptance of the model contributory scheme for hospital benefit, and the memorandum on interpretation of the policy in connexion with radiological services—the former, as Mr. McAdam Eccles remarked, long overdue—showed agreement as to the immediate applicability of the policy to new as well as to old-standing problems. The only major modification effected in the report as presented by Sir Richard Luce was the reference back for further consideration, on the motion of Newcastle, of the detailed classification of hospital patients. The discussion under this head illustrated once again the difficulty of framing a formula applicable to all the widely differing hospital conditions throughout the country. Decision seemed to turn upon considerations of immediate expediency rather than upon any question as to the general accuracy of the proposed classification. The determining factor was probably the fear that the comprehensive analysis of existing conditions might lessen the value of the policy as an instrument for securing the modification of those conditions in the desired direction. The financial statement this year presented no outstanding features. It was accepted with the usual appreciation of the Treasurer's qualities in exposition and debate no less than in finance. A question from Dr. W. Griffith allowed Mr. Bishop Harman to submit an interesting analysis of expenditure on the advancement of science, showing that over one-half of the annual income of the Association is directly allocated to this object. Sir Robert Bolam's statement on the progress of building at Tavistock Square required this year no particular elaboration or comment. His presentation of the report on the progress of the *British Medical Journal*, and his tribute to the success achieved during the past year, was heard with warm appreciation. His reference to the great increase in the number of careful and critical readers of the *Journal* received some confirmation from the discussion raised by the well-argued plea of Edinburgh and Leith for further improvement in certain directions. The speakers fully understood that the desired improvements would have to be paid for; they were equally convinced that money so spent would be an excellent investment. The session ended punctually with the introduction of the report on the agreement arrived at by the series of conferences on the salaries of whole-time public health medical officers held between representatives of the British Medical Association and representatives of local authorities since the beginning of the year, under the chairmanship of Lord Askwith. This arrangement of the business gave members of the Representative Body an excellent opportunity of assimilating the contents of a document of unusual importance before entering upon any discussion of its features.

Saturday, July 20th.

The first business for Saturday morning was consideration of the agreement reached by the conference on public health salaries. The reception accorded to Sir Robert Bolam's report on the memorandum must have been an ample recompense to him and the other representatives of the British Medical Association for the labour spent on its formulation. The scheme embodied is admittedly incomplete, and was subjected to frank criticism on that score. At some points and in some respects, as Sir Robert Bolam pointed out, it even falls short of the conditions which the Association has been able to impose in recent years in an

increasingly large number of cases, but it was welcomed by public health members and by the main body of the representatives alike in no uncertain terms, as offering a sound basis for the development of the public health service. When Dr. D'Ewart's voice was raised with its accustomed vigour, not in castigation of the Council, but in benediction, there was little need to anticipate adverse criticism. The chief virtue of the scheme, according to Sir Robert Bolam's exposition, lies in the atmosphere of common concession in the public interest wherein it is conceived. If it is considered by local authorities in an atmosphere in any way comparable to that in which it was accepted by the Representative Body, there need be little doubt as to its success as a basis of settlement. Dr. Bone had this year an unusually light task in handling the medico-political report. On the Council's recommendation as to the propriety of neither asking nor accepting fees for help in the investigation of maternal mortality set on foot by the Departmental Committee, there was just sufficient opposition to lend importance to the decision. The meeting showed no inclination to follow St. Pancras in an attempt to upset the position of equilibrium based on last year's decision as to contract fees for juvenile Oddfellows, though feeling still runs high whenever club practice conditions come under review. On the subject of fees for attendance on road accidents the Representative Body, heartened by the pertinacity of the Representative for Aberdeen, and fired by Dr. J. B. Miller's glowing picture of the police force acting in this matter as fee collectors for the profession, refused to accept the Council's plea of *non possumus*. Under the same leadership they showed themselves equally determined to surmount the difficulties involved in the formulation of standards of fitness for applicants for driving licences. On the vexed question of the restrictions on the use of heroin imposed by the latest Dangerous Drugs Regulations, Dr. Bone was enabled, by his intimate knowledge, both of the history of the offending restrictions and of the actual provisions of the Regulations, to emerge unscathed from a heavy fire of criticism. The one resolution actually passed in this connexion was calculated to help the Council in its attempt to secure reconsideration of an irksome and unnecessary restriction on medical practice.

The debate on the national maternity service scheme for England and Wales was maintained at a definitely higher level than any which had preceded it, a fact due in part, at least, to Dr. Dain's admirably direct and balanced introductory speech. The scheme was submitted "not as an endowment scheme for doctors," but as a serious and timely contribution to an urgent national need. As such it was criticized and subjected to the test of local experience, and the tone of the debate should in itself go far to satisfy Sir Ewen Maclean that what he characterized as the essential condition of its successful application—namely, the active good will of the general practitioners of the country—will not be lacking. Questions of cost and remuneration were canvassed, it is true, but in the main only because their right adjustment is a factor of efficiency. The acceptance of the scheme in its entirety, with a minimum of agreed modification and addition, was a triumph for the committee and its chairman. Incidentally, the debate was enlivened by a maiden speech from Dr. B. H. Pain of a quality warmly appreciated by the Representative Body. Discussion of the Psycho-Analysis Committee's report, concisely presented by Dr. Langdon-Down, was cut short by the hands of the clock. The heat of the room and the lateness of the hour might have excused a certain apathy; but of apathy there was none, either in the brief speeches by Dr. Parry and Mr. Turner and by Dr. Biggs and Dr. Gordon, or in the applause that greeted these statements of opposing points of view.

The Manchester War Memorial.

Just before the representatives left for their excursion to Chester and Eaton Hall on Sunday, July 21st, they gathered at the Manchester War Memorial in St. Peter's Square, at the foot of which a wreath was laid on behalf of the Association. The simple ceremony was performed by the President-Elect, Professor Arthur H. Burgess. The wreath, a large and beautiful one of lilies and carnations, bore a card stating that it was a tribute from the British Medical Association, visiting Manchester, in remembrance of Manchester's fallen.

The Overseas Luncheon.

On Friday, July 19th, the representatives of the Overseas Branches and Divisions visiting Manchester for the Annual Representative Meeting were entertained to lunch at the Queen's Hotel by the four officers of the Association, the chairman of the Organization Committee, and the chairman of the Dominions, India, Colonies, and Dependencies Committee. The other guests included Professor A. H. Burgess, President-Elect, Professor W. Harvey Smith, who will preside over the Annual Meeting next year in Winnipeg, Sir Jenner Verrall, Sir Malcolm Watson, Colonel Ashton Street, Dr. E. Bosdin Leech, Dr. R. G. McGowan, Mr. Oswald Hempson, and the senior officials of the Association. Dr. C. O. Hawthorne, who took the chair, explained that this was not in any sense a formal part of the proceedings at Manchester, but a brief opportunity for cultivating good fellowship and getting to know workers from different parts of the Empire. In welcoming most cordially the overseas representatives, he wished to assure them of the gratitude felt by the Association at home for the hospitality and kindness shown to those from headquarters who had paid official visits to the Dominions and Colonies. Dr. Hawthorne asked each visitor to stand up in his place for a moment as his name was read from the list, and ended with a few happy phrases by way of introduction between hosts and guests. The luncheon party ended with brief replies by Dr. Gordon Anderson, who conveyed the best wishes of his colleagues in New Zealand, and by Dr. N. C. Sikri, who said that a gathering like this at Manchester made him feel what an honour it was to belong to such a great professional body as the British Medical Association. The names and constituencies of the overseas guests present are: Dr. E. Gordon Anderson (New Zealand, Wellington), Dr. A. B. Black (Southern Transvaal, Johannesburg), Dr. A. S. Erulkar (Bombay), Dr. Dunbar Hughes (Grenada), Dr. H. Huff Johnston (New South Wales), Dr. G. W. R. Ross (Mashonaland), Dr. Eustace Russell (Queensland), Dr. H. B. Savage (Northern Transvaal, Pretoria), Colonel J. A. Shorten (Calcutta Branch), Dr. N. C. Sikri (Punjab), Dr. H. C. Sinderson (Mesopotamia), Dr. H. Douglas Stephens (Victorian Branch), Dr. R. Y. Stones (Uganda), Dr. G. C. Strathairn (Jamaica).

General Medical Council Election.

At the Representative Meeting on Monday afternoon the Chairman (Dr. Hawthorne) announced that the vote of representatives on the names of candidates to be supported by the Association for the forthcoming election of two direct representatives for England and Wales on the General Medical Council had resulted in the selection of Dr. H. B. Brackenbury and Mr. Bishop Harman. The announcement was received with applause. The Chairman added that it might be concluded that these two gentlemen would "shine in the firmament" of the General Medical Council from January 1st, 1930. The satisfaction which was felt with regard to these nominations was qualified by the fact that a star of considerable magnitude would disappear from that firmament—he referred, of course, to

Sir Jenner Verrall, who had occupied a position on the General Medical Council for, he believed, eighteen years. There were others in the meeting who were able to speak with close and detailed knowledge of the services Sir Jenner had rendered, but all of them, without that specific and detailed information, had a sufficient general knowledge of his character, his achievements in connexion with the British Medical Association, and the services he had rendered to the public interest, to be perfectly certain that in discharging his duties as a representative, not of the Association, but of the medical profession, on the General Medical Council he had acquired the respect, regard, and confidence of every member of that Council, and had more than justified the confidence placed in him by the voices and votes of his fellow practitioners. The Association was not saying good-bye to Sir Jenner Verrall; it was merely that, as he had served the profession and the public so admirably in a particular capacity, the Association could not allow him to terminate that function without according him a cordial vote of thanks. At the same time, knowing he was to be released from that duty, the Association counted all the more confidently on the number and variety of services he would render it in the future. The motion he desired to propose was as follows:

> "That on the occasion of the retirement of Sir Jenner Verrall, LL.D., after eighteen years' service as a direct representative on the General Medical Council, the Representative Body desires to place on record its deep appreciation of his valuable work for this profession in this special field of service, whilst sincerely hoping he may long be spared to increase the debt which the medical profession of this country in general, and the British Medical Association in particular, owe to him for counsel, for inspiration, and for leadership."

The Chairman of Council (Dr. Brackenbury) said it so happened that in the absence of Sir Robert Bolam he was the senior member present of those sitting on the General Medical Council. He did not propose to repeat the eulogy the Chairman had expressed in such felicitous terms, but he thought it right that one who had watched Sir Jenner Verrall as a member of the General Medical Council should say how much the profession of this country owed to his work and influence and advice in that body. Mr. E. B. Turner, as one who had been associated with Sir Jenner Verrall on the General Medical Council for five years, cordially welcomed the proposal to accord him a special vote of thanks. Sir Jenner Verrall had often swayed the deliberations of that Council; his words were wise and his vote given with discretion and great intelligence. He tempered justice with mercy, and was always willing to do anything in his power for the honour and interest of the profession he represented. Now that he was retiring with honour from that position the Council would lose one whom it could ill spare, and the loss to it would be as great as the loss to the profession. The vote of thanks was carried with acclamation, and Sir Jenner Verrall, who was received with loud applause, briefly responded.

The Religious Service.

The official religious service in connexion with the Annual Meeting took place on Tuesday afternoon in Manchester Cathedral, when the sermon was preached by the Archbishop of York (Dr. Temple), who was until recently Bishop of the diocese of Manchester. The President, officers, and members of the Association assembled and robed at the Grammar School near by, and from there a procession was formed, headed by the Ceremonial Staff which had just been presented by the Treasurer. Those attending the service included the Lord Mayor of Manchester, the Mayor of Salford, the Chancellor and Vice-Chancellor of the University, and representatives of the nursing profession, St. John Ambulance, and the British Red Cross. The lesson (Romans xii, 1–18) was read by the President, and a special thanksgiving prayer was offered for the King. The Archbishop began his sermon by saying that the marvellous advance of science, which was at once the most pronounced characteristic of the period in which we lived and the chief influence upon the thoughts of men in this period, impressed those who had any religious faith at all with an ever deeper sense of the infinite majesty of God. On the other hand, in its first impact such a growth in knowledge was very liable to create a sense of personal insignificance, and thereby to paralyse the sense of responsibility which was a necessary part of the life of a religious man. As men became more closely acquainted with the vast ranges in time and space that were opened up by scientific researches, it was difficult to realize that the lives they themselves lived could be of any very great or ultimate significance. Their forefathers were often inclined to suppose that divine manifestations were only recognizable in connexion with occurrences where their own knowledge as to their causes failed. Where they could not trace those rational connexions between events to which the term "explanation" was applied, they propounded a hypothesis of Divine intervention. Having learned to see God chiefly in the gaps of human knowledge, they inevitably felt, as knowledge filled in those gaps, that the sphere of Divine action was being curtailed, and they began to wonder whether, with still more knowledge, they might not be able to dispense with God altogether. A very large amount of the agnosticism of the later nineteenth century, added the Archbishop, was the inevitable result of the habit which religious men had unconsciously adopted of limiting the Divine action to those regions where no other explanation of what took place was forthcoming. But that was not a view of the world which could be logically associated with belief in "God Almighty, Maker of heaven and earth, Creator of all things visible and invisible." If only men had trusted more confidently to the faith they professed they would have seen in every advance of science, not an exclusion of God from the world He had made, but only a further explanation of the way in which God did all His work. All new knowledge of the world was, and ever must be, new knowledge of Him. The Archbishop went on to speak of the problem of suffering, one of the two great forms of evil in the world, and the one which medical science was devoted to remedying and preventing. The problem of pain was peculiarly disturbing to those minds and hearts which were otherwise disposed to faith in God. But it was in the suffering of the Son of God that the means was found whereby the world was redeemed, and in the light which that threw upon suffering some gleams were caught of what might be the solution of this mystery. Concluding with a reference to the medical profession, the preacher said that in all the work which was done by that profession God could be seen at work in His world, helping humanity to rise above its customary levels of experience. Physical healing, and the healing of the soul, though best perhaps carried out by separate hands, were not really different ministries; they were one in the purpose of God for His world—a purpose which was "joy triumphant over pain." Following the sermon there was a solemn procession, round the interior of the cathedral, of the choir, clergy, municipal authorities, the Council of the Association, and many medical graduates wearing robes. The Archbishop pronounced his benediction while the remainder of the procession stood in the aisles, and so a dignified service came to an end. The offertory is being devoted to the B.M.A. Charities Fund, with the exception of one-quarter, which will be used to place in the cathedral a memorial of the present Annual Meeting.

A telegram received from Manchester as we go to press announces that up to noon on Wednesday those attending and registering at the Annual Meeting numbered 1,420.

WATER SHORTAGE AND THE PUBLIC HEALTH.

ATTENTION has been drawn by the Minister of Health to the dangers attending the present water shortage—dangers which will not be entirely removed until there has been long-continued and exceptionally heavy rainfall. In his recent memorandum—to which we referred last week at page 119—the warning is given that should the next few months be at all dry there will be considerable risk of scarcity in several districts. In many neighbourhoods at present where the water supply is relatively deep-seated little or no anxiety is being felt, but it has unfortunately to be remembered that even these supplies may suffer severely later on from the drought, perhaps long after the surface supplies have been fully replenished. The abnormally low rainfall since last December has resulted in a greater water scarcity than at any corresponding period since 1921, and we are again being reminded how dependent a modern urbanized community has become on a few fundamental sanitary conditions. Among the most important of these are a continuous and adequate supply of pure water, and the rapid removal of waste products, the accumulation of which among collections of human beings is incompatible with healthy life. Apart from the consequent interference with industry the ordinary intensive conditions of city life cannot be maintained in the absence of a sufficient water supply. Diminished rainfall results inevitably in the streets becoming dirtier; the flushing of gulleys, drains, and sewers is decreased, or even stopped altogether. The resulting accumulations in these conduits are extensive and foul; they constitute a serious insanitary condition, which it is impossible to deal with. This being the case, no surprise will be felt that the Minister of Health insists that there must be no delay in conserving existing water supplies wherever a shortage exists or is threatened, since new supplies cannot usually be improvised at short notice. Moreover, it is mentioned in the memorandum that statistics now available for a long succession of years indicate that the rainfall during the next few years may continue to fall short of the average. The problem is, therefore, not to be dismissed even with the incidence of some days of heavy rain. The first consideration, doubtless, is the supplementing of the existing supplies, but this is not often possible, and accordingly attention has to be directed to the economical use of water and the prevention of remediable waste. As an illustration, it is suggested in the memorandum that there is much to be said for providing new washers to defective taps without charge to the consumers, since the small cost of this will be amply met by the saving in water. The voluntary curtailment of domestic supplies in respect to the watering of gardens and the washing of motor cars may be made a little less irksome if it is realized that voluntary co-operation in this way by individual householders may prevent the imposition of definite restrictions later on. The important matter of "*compensation* water" is not overlooked, and it is suggested that agreements for the temporary reduction or intermission of discharges will often divert large quantities of water to the domestic needs of the public. Wherever available, supplies of non-potable water should be used for street watering and the flushing of drains. Every effort has to be made to prevent intermitting the domestic supply, since there is always some risk of contamination where pipes are not fully watertight, or when the influx of impure water is possible. Chlorination, though the readiest means of purifying water, should only be employed under expert supervision. In the last resort, particularly in rural parishes where the residents use shallow wells and similar sources, the importance of boiling water should be emphasized if there is any serious danger of pollution. The Minister of Health adds that where expense has to be incurred by a local authority in relieving water shortage in its district, the county council is empowered by Section 57 of the Local Government Act, 1929, to contribute towards this expenditure. Similarly, district councils are empowered by the preceding section of this Act to contribute towards the expenses, which would otherwise have to be defrayed by a special rate upon the place concerned. Co-operation between adjoining districts will undoubtedly help to solve some local problems, and emphasis is laid on the advantages of forming regional advisory committees on the lines indicated by the booklet which was issued by the Minister of Health last October.

SIR WILLIAM OSLER'S LIBRARIES.

THERE has lately been published by the Clarendon Press "Bibliotheca Osleriana: a catalogue of books illustrating the history of medicine and science, collected, arranged, and annotated by Sir William Osler, Bt., and bequeathed to McGill University."[1] It is an exceedingly fine example of cataloguing, indexing, and printing. The eight sections into which the catalogue is divided were Sir William Osler's own arrangement, and it had been his intention to write a special introduction to each section to "explain to students how they are to be used." These introductions unfortunately were not written, and their place is taken by a more general preface by the editors, W. W. Francis (librarian, Osler Library), R. H. Hill (Bodleian Library), and Archibald Malloch (librarian, New York Academy of Medicine). The idea of the Bibliotheca Prima, which is the chief feature of the library and of the catalogue, was outlined by Sir William Osler in a leaflet in 1919; it is "to have in a comparatively small number of works the essential literature grouped about the men of the first rank, arranged in chronological order." This unusual arrangement is carried out in an interesting and very informative way, and many of the items are in themselves of a fascinating character in their biographical and historical details and incidental comments. The same is true of the entries in the other sections, though these are arranged in the more usual way, in the main alphabetical. Besides the editors' preface there is an introduction entitled "The Collecting of a Library," written by Sir William Osler himself, and to this is appended a note on "A Record Day at Sotheby's," which was intended by the author to be incorporated in some form in his introduction which was left incomplete. This essay, covering in print less than twelve large pages, should not be missed by anyone who cares for literature, for libraries and books, or for the work and memory of Sir William Osler. It is a brief account of his introduction to, love for, and dealings with, books from his days in "a country parson's house in Canada in the 'fifties and 'sixties" to his disposition of those which he owned at his death. George Borrow was, perhaps, his first delight, but "the first book bought was the Globe Shakespeare, the second the 1862 edition, Boston, of the *Religio Medici*, both of which were the close companions of my student days. The Shakespeare was stolen and the curses of Bishop Ernulphus have often been invoked on the son of Belial who took it; the Browne, bought in 1867, is the father of my Browne collection"—a collection which is almost complete and has been kept together. The narrative of another annexation is thus given: "Schmidt's 'Shakespeare-Lexicon' I asked to have sent to me as soon as published. I moved to rooms with Mr. King, who had but one thought in life—Shakespeare. He was a dear old man, much esteemed and always ready to spend more than he could afford on his hobby. One afternoon at the College the postman left a parcel, and to my delight it was Schmidt's Concordance. My first thought was, how happy Mr. King will be to see it. On my return Mr. King greeted me with 'What's that you've

[1] Oxford: The Clarendon Press. 1929. (6s. net.)

got?' 'Something that will rejoice your heart,' I said, and deposited the work in his lap. The shock of the realization of a life-long dream, a complete concordance of Shakespeare, seemed to daze the old man. He had no further interest in me, and not a word did he say. I never got it back! For months he avoided me and he never referred to it again. The work went to McGill College with his Shakespeare collection. When in the library in 1910 I asked for the first edition of Schmidt and was glad to see my book again after thirty-five years." It was, however, with medical and scientific books and libraries that Osler's interests were most intimately concerned, and he takes the reader on a fascinating pilgrimage through the schools and libraries of Weston, Toronto, Montreal, Philadelphia, Baltimore, and Oxford, with incidents from Berlin, Vienna, and London on the way. A particular seat in the Bodleian was evidently his favourite spot, but he tells in a beautiful passage why he felt drawn to make his bequest to McGill—"the formative years were there with the strong ties of head and heart." He introduces us on the journey to many of his teachers, comrades, and friends, including librarians and founders of libraries, for "a library is usually the result of the enthusiasm of one or two men." A library, he says, "represents the mind of its collector, his fancies and foibles, his strength and weakness, his prejudices and preferences. Particularly is this the case if to the character of a collector he adds—or tries to add—the qualities of a student who wishes to know the books and the lives of the men who wrote them. The friendships of his life, the phases of his growth, the vagaries of his mind, all are represented." So in this catalogue of his books—even though we have not the names of those "left over, a motley collection of miscellaneous works which may remain in the house to help fill the shelves"—and in this introductory essay, we really feel the charm, the attraction, and some of the value of the author and collector himself.

THE TRAFFIC IN DANGEROUS DRUGS.

THE British Government's report for 1928 to the League of Nations on the traffic in opium and other dangerous drugs contains information as to the working of the system of control which has been established in this country in accordance with the Hague and Geneva International Conventions over the trade in dangerous drugs, and as to the action taken by the Government in co-operation with other Governments to suppress the illicit traffic. No seizures of importance occurred in Great Britain during the year, and the year's record helps to confirm the experience of previous years that illicit traffic in drugs exists in this country only on a very small scale. The reports of seizures received from British Colonies, from the British Dominions, in particular India and Canada, from the United States of America, and (through the secretariat of the League) from other countries, showed, however, that the illicit traffic in drugs was being carried on vigorously throughout the year, and that great quantities of these drugs were smuggled, particularly to North America, Egypt, India, and China. Great Britain has continued to work in close co-operation with the authorities in the Dominions (particularly Canada and India), the Colonies, the United States of America, and other countries with a view to the suppression of this traffic. Tables in the report show that the output of morphine in Great Britain has decreased by over 23,000 ounces on the figure for 1927. The exports have also decreased by nearly 18,000 ounces, and are now about one-half of what they were five years ago. The output of heroin is also down, and the exports touched the lowest figure yet reached—6,038 ounces. France took 3,244 ounces less of heroin last year than in 1927. About three-quarters of the opium used in the manufacture of drugs in this country is now Indian; one-quarter is Turkish. Practically no Persian or Serbian opium is now being used. For the first time a large proportion of Great Britain's supply of cocaine was made in the country. The output for the year was 4,934 ounces; the imports totalled 9,353 ounces, being some 6,000 ounces less than the imports during 1927. During the current year the output in this country will be increased and the imports correspondingly decreased.

WHITE AND BROWN BREAD.

EVERYONE knows that what he sees printed in black-and-white may be if not a black lie, a white one; but the popular faith in printed figures, especially when these are marshalled in impressive tables, reduced to percentages, and corrected for all sorts of errors, dies hard. It is difficult even for statisticians to remember that the validity of such tables depends entirely on the precision of the data out of which they had been constructed, and that no form of mathematical treatment has yet been discovered which will produce an accurate synthesis from inaccurate figures. As a case in point may be cited many of the generally accepted estimations of the carbohydrate content of common foodstuffs, which, according to Dr. R. A. McCance and Dr. R. D. Lawrence, the authors of *The Carbohydrate Content of Foods*,[1] are often out by several hundreds per cent. Their repudiation of the analysis given in the tables in current use will probably come as a painful shock to those who, armed with slide rules, have laboured long and faithfully, working out from them detailed balanced diets for their diabetic patients. The authors do not confine themselves, however, to destructive criticism, but devote the first part of their work to tables in which are presented corrected analyses of the available carbohydrate content of fruit, nuts, and vegetables. In the second part of the paper they deal with the nutritive properties of vegetable fibre, and, from the fact that a considerable proportion of ingested cellulose disappears from the gut they conclude that the laxative action of cellulose and that of cell membranes cannot simply be due to their addition of bulk to the faeces, but to the stimulant action of the products which result from their fermentative digestion. Of more general interest is their discussion of the dietetic value of wholemeal bread: "Discussions on the relative merits of white and wholemeal bread," they write, "are usually directed more by psychological bias than by experimental facts. People who neither know the facts nor are able to appraise them, people with vested money interests and cranks of all kinds, speak and write freely on the subject with ever-recurring waves of enthusiasm. So few of the facts, however, seem to be generally known and the position could so fitly be discussed here, that we have devoted a section to the subject." After this introduction we learn without surprise that the authors are unfavourable to the use of wholemeal bread. They remark that when allowance is made for the food calories lost in the faeces, wholemeal bread has a lower calorie value than white bread; and the argument that, white bread being deficient in vitamin B, its consumption is a common cause of digestive disorders, they meet as follows: "If the vitamin deficiency of white bread were the cause of so much constipation and the vitamins of wholemeal bread were the specific cure, then this could hardly have failed to attract the attention of physicians and the public, neither of whom are slow to apply such simple remedies." This argument, that a new idea cannot be true, because if it were true someone would have thought of it long ago, has been advanced against every new idea since the dawn of history, and we confess to some surprise at finding it in a serious scientific publication. We hold no brief for white bread

[1] *The Carbohydrate Content of Foods.* By R. A. McCance and R. D. Lawrence. Medical Research Council. Special Report Series No. 135. Price 2s. net.

or brown, but suggest that the authors would have done well to examine their own rationalizations a little more carefully before directing attention to the "psychological bias" of other people. It is true that the validity of the evidence which has been brought forward to support the claim that vitamin B deficiency causes intestinal disorders is questioned by many workers of repute; until, however, this evidence has been definitely refuted it should not be ignored. The authors' final conclusions are sound: "Children," they write, "are very intolerant of high cellulose diets, and, for some, brown bread is far too irritating, even if given with the idea of relieving constipation. Appetite is such an important factor in all digestive considerations that no one who dislikes a food of unproved value should be forced to eat it if it can be avoided. In time of peace, of course, the grown-up population, if they have the choice, will never eat wholemeal bread unless they like it, no matter how specious the advertisement, but they may force their children to eat it in the belief that they are doing them good. One should, therefore, be cautious in advising wholemeal bread generally, and wait until careful unbiased experiments have been done on a sufficient number of men, women, and children. Thus only can accurate conclusions be drawn."

"MYOCARDIA."

PROFESSOR EMILE SERGENT has recently sponsored an interesting volume of lectures delivered in his clinic in Paris by his colleagues, former pupils, and distinguished visitors, and the result is eighteen essays in the delightful clear style for which French clinical medicine is famous.[1] Any of these essays would provide material for comment: one of the most striking, with interesting practical bearing, is on the subject of "myocardie," for which the English word "myocardia" is suggested. This term, which is new to medicine, was introduced in recent years by Laubry and Walser, who wished by it to describe a type of primary cardiac failure of unknown origin. The word "myocarditis" is frequently applied to cases of cardiac failure, especially if the exact etiology is unknown, but careful pathological investigation of cases that come to autopsy may fail to reveal any evidence of gross inflammation of the heart muscle, either acute or chronic, and such small changes as are found may be quite well explained as post-mortem effects. It was to avoid the use of the term "myocarditis," with the implications carried by its ending, that the French workers began to talk of "myocardie," which has no such etiological significance. Professor Francis Bordet, in one of the lectures in this volume, discusses the diagnosis of myocardia, basing his remarks on the case of a man, aged 35, who died from rapidly advancing heart failure for which no obvious cause could be found in life. This patient suffered from shortness of breath on exertion; he had cyanosis of the face, and there were also present signs of stasis in both the systemic and pulmonary circulations, pulsation of the jugular veins, oedema of the back and legs, and enlargement of the liver. The heart was enlarged, and an *x*-ray examination showed this to be due to dilatation of both ventricles; the pulse was rapid and irregular, with gallop rhythm heard on auscultation. The history of the patient before admission to hospital was to the effect that only four months previously he had noticed some difficulty in climbing a steep hill, and from that time onwards progress of the heart failure had been rapid. Rest and digitalis therapy had proved useless, and at the time of Professor Bordet's lecture the patient had to be propped up in a sitting position. No etiological factor could be found to account for this failure, except that during the war the patient had suffered from a gunshot wound of the left side of the chest with a haemothorax, and the left side of the diaphragm did not move as well as the right side. There was also a doubtful history of alcoholism. In view of these two possible factors in the causation of the cardiac failure, Professor Bordet considered that the case of this patient could not be regarded strictly as of pure myocardia, but would come under the category of associated myocardia, a term reserved for cases of cardiac failure where an etiological inquiry is not entirely unproductive, but where such factors as are present do not appear sufficient to account for the severity and rapidity of the evolution of the disorder. Not long after the delivery of this lecture Professor Bordet's patient died, and at the necropsy the heart was found to be dilated, all the cavities being affected. There was no disease of the aorta or coronary arteries, and microscopic examination showed no evidence of myocarditis. Such is the usual finding in cases of myocardia, and the exact pathogenesis remains obscure. It is suggested that the condition is due to a cardiac hypotonia, possibly connected with the nervous system and muscle tone, and brought on, perhaps, by emotion or physical strain. It is always a serious matter to introduce a new term into medicine, but non-inflammatory disorder of the cardiac muscle cannot be satisfactorily classified as a myocarditis, so that there is some justification for the use of the term "myocardia." The diagnosis of this condition is largely by the unsatisfactory method of exclusion, and in any case it is not a diagnosis to be lightly proffered in view of the serious prognosis.

CO-OPERATION BETWEEN THE MEDICAL PROFESSION AND THE MINISTER OF HEALTH.

ONE of the first acts of the present Minister of Health (Mr. Arthur Greenwood) has been to enlarge the very wide range of the various forms of consultation which already subsist between the Minister and the medical profession. This extension of contact between the Government and medical opinion takes shape in the appointment, in a purely personal capacity, of Sir John Rose Bradford, Lord Moynihan of Leeds, Lord Dawson of Penn, and Dr. H. B. Brackenbury as a small informal committee to confer from time to time with Sir George Newman, the Chief Medical Officer of the Ministry of Health. The object of the conferences will be to give ample opportunity for the committee to place before the Minister their views on any current medical matters about which they desire him to be specially informed, and for the Minister to consult the committee with the same case. Mr. Greenwood has added that he hopes personally to find in this arrangement a ready means of communication between the committee and himself as occasion arises; and that it will contribute to the close, continuous, and sympathetic association which he desires to see maintained between the medical profession and the Minister.

THE INTERNATIONAL MEDICAL CLUB, NEW YORK.

THE International Medical Club of New York is an institution which aims at the promotion of social and scientific relations between American medical graduates and medical practitioners of other countries who are visiting, residing, or practising in the United States. It keeps in close touch with the various medical societies in that country, and is therefore in the position to advise and assist medical practitioners who are touring and wish to visit medical institutions. The club has interested itself particularly in medical progress in foreign countries, and has a number of corresponding members in Europe; information is made available also as regards post-graduate instruction in Great Britain. Members of the British medical profession who would like to know more about this institution should write to the chairman of the Liaison Committee, Dr. F. H. Allbee, 30, East 40th Street, New York City.

ROYAL SANITARY INSTITUTE.

CONGRESS IN SHEFFIELD.

THE fortieth congress of the Royal Sanitary Institute was held in Sheffield from July 13th to 20th, and was attended by over one thousand delegates, including more than sixty from the Dominions and foreign countries. The president of the congress was EARL FITZWILLIAM, who devoted his address from the chair to a sketch of recent sanitary progress. The congress met in six sections, and, in addition, there were six conferences for different categories of administrators and social workers.

Child Guidance.

The Section of Preventive Medicine, presided over by Professor ARTHUR HALL (who expressed some distrust of the term "preventive medicine" as likely to frighten the man in the street because it suggested another medical preserve), devoted itself entirely to mental hygiene. Dr. R. H. CROWLEY, senior medical officer, Board of Education, described the principles and practice of the child guidance clinic. He said that a great deal of pioneer child guidance work had been carried on in London, and clinics on modest lines were at work in several places in the provinces, connected either with the local education authority, the hospital, or the university. These were beginnings of activities likely to develop into a great national service. Dr. WILLIAM MOODIE further developed this subject, and he was followed by Miss EVELYN FOX, secretary of the Child Guidance Council, who said that the unit of clinic work was one psychiatrist, one psychologist, and three or four social workers. Dr. G. A. AUDEN, school medical officer, Birmingham, spoke sympathetically of "adventure fantasies" and psychopathic conflicts in the "difficult" child.

Mental Hygiene in Adults.

On the subject of mental hygiene from the point of view of the adult, Dr. E. MAPOTHER, superintendent of Maudsley Hospital, contributed a thought-provoking paper. The statistical influence of organic factors in mental disorder, he said, would be almost negligible apart from alcoholism, syphilis, arterio-sclerosis, encephalitis, and epilepsy. In functional mental disorder, as in epilepsy, little or nothing could be done in advance of the symptoms. The factors operative in determining such disorder were congenital make-up, abnormalities of the changes incidental to normal events and epochs of life, and recent or remote experiences. The pivot of the system for early treatment in progressive countries was the psychopathic clinic, of which at present the Maudsley Hospital was the only English example. Wards in general hospitals, municipal or voluntary, could no more replace psychopathic clinics than cottage hospitals could do the work of medical schools. He wholly approved of a voluntary system at public asylums for other reasons, but this would not touch the problem of treating the really early case. Observation centres also were needed for the early treatment of cases objecting to, or too objectionable for, the psychopathic clinic. Direct admission to the mental hospitals had been advocated as a better way of dealing with such cases, but as a matter of experience only 50 per cent. of the cases admitted to observation wards went on to asylums. The observation centre should be sections of one of the municipal general hospitals, and should be large enough to permit of proper classification. Most of these patients would be under some such authority as the provisional order of the Royal Commission.

In further discussion of this subject, Dr. W. VINCENT spoke of the prophylaxis of mental disorder, including the role of alcohol and syphilis as causes, and pleaded for the establishment of a large number of mental clinics at which advice and treatment could be offered in the early stages of mental illness. Dr. R. W. GILMOUR described the role of the general hospital as a centre for mental hygiene. He held that there should be an out-patient department at every general hospital for the treatment of mental cases, with a few beds set aside in the neurological ward for those requiring special care. Examination and treatment should be undertaken by someone doing mental work alone, which would be possible if a liaison were established between the mental and the general hospital.

Maternity and Child Welfare.

The Maternity and Child Welfare Section was presided over by Lady MABEL SMITH, who spoke of the need for a national maternity service. Among the papers read in this section was one by Dr. RON[illegible] mentioned some routine starvation and the giving ventive treatment of summer diarrhoea. In his borough during the last five years there had been 115 deaths of infants due to enteritis, but only five of these occurred amongst those who had received the routine treatment. Dr. ALLEN DALEY (M.O.H., Hull) sketched the manner in which the Local Government Act will affect maternity and child welfare and school medical services. Dr. W. M. ASH described how existing institutions within the county might be utilized for a complete maternity service. He believed it was for the good of all concerned to make the smaller hospitals, scattered about counties, serve wider interests than they were doing at present, and to concentrate at these centres work at present done by a multitude of small uneconomical institutions. He would have these hospitals not only accommodate maternity in-patients, but provide for midwifery and sick nursing in the area around them. The hospital should be the centre of the ambulance service, and also the centre from which accouchement outfits could be distributed to necessitous cases.

Dame LOUISE MCILROY dealt with the influence of syphilis on pregnancy, describing and commending the system of co-operation between the obstetric and venereal diseases departments of the Royal Free Hospital; and she was followed by Dr. MARGARET ROBIE, who said that at that hospital during the last five years there had not been one child stillborn or showing signs of congenital syphilis at birth or soon after where the mother had had treatment during pregnancy. Mr. JOHN ADAMS, F.R.C.S., who gave some account of the good work at Thavies Inn, urged that the authorities should provide hospitals for in-patient and out-patient syphilitic pregnant women, which would also be training schools for the treatment of ante-natal and post-natal syphilis. All pregnant women in hospitals and public institutions should have a blood test on admission.

National Health Insurance and Other Subjects.

A conference on the national health insurance services was presided over by Mr. STANLEY L. DUFF, chairman of the approved societies' consultative council. He referred to the question of medical certification and the rise in claims for sickness benefit. The recent proposal to treat as an infraction of the medical benefit regulations the issue of medical certificates without the exercise of due care was one which should command the support of all practitioners whose obligations and relationship to the health insurance scheme were rightly conceived. The discussions in this conference were non-controversial, relating to such subjects as health education, convalescent treatment and after-care welfare, and the education of officials in the national insurance service.

In a discussion on the progress of cremation, which, he said, was much slower in this country than in Germany or America, Professor BOSTOCK HILL complained of the attitude of the British Medical Association in preventing the proper functioning of an arrangement whereby in several populous localities medical practitioners of standing could give the necessary certificates at a reasonable fee. Excessive fees had been charged for certificates in the past, and as the final responsibility in the matter rested with the medical referee appointed by the Home Office, no onus requiring an excessive fee was placed upon the practitioner.

The increasing frequency of abortion, and also of pneumonia without previous symptoms, as causes of sudden death was the subject of a paper by Mr. C. J. HAWORTH, coroner for the West Riding. He mentioned that in his area over fifty sudden deaths from pneumonia, in which there were few or no symptoms of previous illness, had taken place within six months.

A section was devoted to hygiene in industry, over which a great industrialist, Mr. W. L. HICHENS, presided. He pleaded with his fellow industrialists for a keener interest in these problems. Artificial industrial illumination, the rural worker and housing, and the social and economic

effects of raising the school-leaving age were the subjects discussed in this section.

Even this does not by any means exhaust the subjects placed before the Congress. The planning of the mental hospital was also discussed: the whole opinion being in favour of villas of moderate dimensions rather than great blocks of several stories. Other subjects were the Sheffield water supply, asphaltic roads and their influence on health, the smoke problem, improved methods of disposal of refuse, reconstruction schemes under the Housing Act, the evolution of the sanitary inspector, biological education as an essential factor in the creation of a public health conscience, regional planning, main drainage schemes, meat inspection, milk hygiene, conditions in bakeries, rivers pollution—the mere recital shows how big a brood the Royal Sanitary Institute has under its wing and how manifold are hygienic implications in modern life.

THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE OPENING CEREMONY.

THE new building of the London School of Hygiene and Tropical Medicine, of which we gave a description in our last issue (p. 117), was declared open at noon on Thursday, July 18th, by the Prince of Wales. His Royal Highness was received at the main entrance in Keppel Street by Lord Melchett (chairman of the Board of Management), Sir Holburt J. Waring, F.R.C.S. (chairman of the Court of Governors), and Sir Gregory Foster (Vice-Chancellor of the University of London). After the architects (Mr. P. Morley Horder and Mr. Verner O. Rees) and the director of the School (Dr. Andrew Balfour) had been presented, His Royal Highness proceeded to the main library, where a large and distinguished company, many of them in academic dress, had assembled.

Lord MELCHETT, in the course of his Address of Welcome, made grateful reference to the generosity of the Rockefeller Trustees, whose benefaction had made it possible to embark on this great enterprise. Their traditional policy of self-effacement explained the absence of the Trustees from the opening ceremony. Nevertheless, he wished to say that the whole British nation and all other nations were under a great debt of gratitude to the Rockefeller Foundation for the gift of this magnificent building. Lord Melchett then briefly outlined the history of the School, and recalled that the foundation stone of the building had been laid three years ago by his successor in the office of Minister of Health, Mr. Neville Chamberlain, whom he welcomed at this ceremony, together with Mr. Arthur Greenwood, the present Minister. He welcomed also the Dominion High Commissioners and other distinguished visitors from overseas, among them the Turkish Minister of Health (Dr. Refik Bey). Their presence was a reminder that hygiene knew no frontiers.

The PRINCE OF WALES, in his reply, said that if the laboratories, museum, and lecture rooms made good the promise of its library the School was indeed to be congratulated, and the building would be a notable addition to the homes of learning in London. Reference had been made by Lord Melchett to the part played by America, and to the duty which lay both on the British Government and on the British people to see that the London School of Hygiene was worthily endowed and maintained. The building was a sign that post-graduate education in medicine was about to come into its own. The establishment and endowment of this centre of teaching in preventive medicine was a signal example of the bond between the two great English-speaking races of the world. The research and teaching carried out there would find its results wherever man lived and moved and had his being. His Royal Highness said in conclusion: "We now stand in the early days of an era of preventive medicine, in which the progress made in sanitation and care of the individual will be developed, and fresh research will lead to the solution of problems not yet solved and to the prevention of much ill health. The establishment of this School is of special importance to the British Empire, and it has undertaken great responsibilities. In my travels I have discovered at first hand the appalling loss of life and effort due to tropical diseases; and I have realized how great is the need for research in tropical medicine and hygiene. In the cause of hygiene generally the School will help and develop the growing work that has already been done. For these reasons I believe that the establishment of this School provides a great opportunity for this country and for the whole world. If its work is properly conceived and carried out there should follow a special development and interest, and a quickening of the public conscience, which will lead to a steady decrease in preventable diseases, suffering, and death. By its work in this connexion the School will be judged."

His Royal Highness then formally declared the building open, and after a fanfare of trumpets sounded by the Coldstream Guards, the Chairman of the Court and the Vice-Chancellor expressed to the Prince the thanks of the governors of the School and of the University of London for his attendance and his sympathetic interest in the work of the School. A point made by Sir HOLBURT WARING was that in planning the building, and at all stages throughout its erection and equipment, they had kept clearly in view that the primary and essential purpose of the School of Hygiene was to serve as a workshop. Their architects had thoroughly grasped that idea, and with it the associated idea that space and light were primary considerations. Sir GREGORY FOSTER said that the school, as a part of the University of the capital city of the Empire, would add to the glories of the University of London, and help to maintain and extend its tradition of service in the cause of humanity. From the colleges and medical schools of that University many men had gone forth whose zeal and skill had made the world a better and a happier place. Foremost among these was Lord Lister, who received his medical training in London and was a graduate of its University.

The Prince of Wales then paid a visit to the museum, laboratories, and lecture theatre, and the guests were entertained at luncheon by Lord Melchett. Later in the afternoon they were shown round the building by the director, the professors, and other members of the staff, and short cinematograph displays were given in the large theatre.

ROYAL MEDICAL BENEVOLENT FUND.

AT a recent meeting of the committee of the Royal Medical Benevolent Fund, thirty-nine grants were made, amounting to £612 1s. It is the hope of the committee that financial help will never be refused to a deserving case, but to be in a position to meet the ever-increasing demand the committee urgently appeals for the support of new subscribers. The summaries given below of a few of the cases recently helped clearly show what abject poverty some applicants have to endure. Subscriptions and donations should be sent to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, W.1.

The following are short notes on six of the cases helped by grants and annuities at the last meeting.

Widow, aged 72, of L.R.C.P., M.R.C.S., whose husband received an annuity from this Fund during the last years of his life. On his death his widow had only the old age pension of £25. Voted £35. Her total income is therefore only £62 a year. Further assistance is being sought for this lady.

Widow, aged 80, of M.R.C.S., L.S.A., is totally blind. She has an income of £77 a year. The Fund voted £36, making a total income of £113, on which the widow and two daughters have to live. One daughter has to give her full time to looking after her mother, owing to her infirmities; the other is trying to find work, but as she is 47 years of age she has been unable to get employment as a clerk.

Widow, aged 75, of M.R.C.S., L.S.A., has an income of £72 a year. Voted £26.

Daughter, aged 76, of M.R.C.S., with a private income of £20 and old age pension of £26. Voted an annuity of £30, making a total of £76.

Daughter, aged 84, of M.D. No private income, only the old age pension of £26. Voted an annuity of £30, making a total income of £56. This lady lives with her niece, a music teacher, who has to keep and maintain her on the above.

Daughter, aged 73, of M.R.C.S., has only the old age pension of £26. Granted an annuity of £40, making her total income £66.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

BEIT MEMORIAL FELLOWSHIPS.

A RECENT meeting of the trustees of the Beit Memorial Fellowships for Medical Research was held for the election of Fellows and the reception of the annual report.

The honorary secretary, Sir James K. Fowler, M.D., referred in the annual report to the great assistance rendered to the trustees by the late Lord Haldane since its foundation in 1909 and until his death; Lord Rayleigh had been appointed to fill the vacancy thus caused. Reports of the directors of laboratories on the work of the Fellows had been uniformly favourable, and mention was made of the energy which was being devoted to the prosecution of the various researches. There had been an unusual number of resignations during the year under review, due to the appointment of the Fellow in each case to a scientific post of a permanent character; such resignations were, therefore, tributes to the value which attached to the tenure of a Fellowship. Researches were in increasing proportion being directed to problems in scientific subjects relating to medicine, and the secretary, commenting on Dr. Canti's work in connexion with tissue culture, mentioned that Miss Honor Bridget Fell, who last year was elected to a senior Fellowship at the value of £700 a year, had been associated in this work at the Strangeways Research Hospital, Cambridge. A serious difficulty had been encountered by Dr. Hindle in his work on a yellow fever vaccine in which he had been engaged. The practical consequence was that it was much harder to test the preventive value of the vaccine, since it was necessary to use large numbers of monkeys. Efforts were being made to re-establish the virulence of this strain and to obtain others. Further evidence had been obtained showing how serious was the risk of infection to those engaged in this research if they were unprotected. The advisory board believed that the records of the candidates at the present election for Fellowships showed that the standard as regards academic distinctions and subsequent performances was at least as high as in any previous year.

The following were elected to Beit Research Fellowships:

Fourth-year Fellowships (value £500 per annum).—Junior Fellows elected to fourth-year Fellowships: (1) Richard James Lythgoe; (2) Maurice Walter Goldblatt.

Junior Fellowships (value £400 per annum).—(1) Robert Hill, M.A.; subject: the specificity of haemoglobins and the function of pigments in cell respiration; (2) Ann Bishop, M.Sc., Ph.D.; subject: morphology and development of trichomonas and other intestinal protozoa; (3) Cuthbert Leslie Cope, M.B., B.Ch.; subject: diuretics and renal function; (4) Leonard Ernest Bayliss, Ph.D.; subject: metabolism of the isolated heart and kidney; (5) Walter Phillips Kennedy, B.Sc., D.Ph.; subject: ovarian function; (6) Eric Boyland, B.Sc.; subject: the mechanism of carbohydrate metabolism; (7) Edwin Martin Case, B.A.; subject: the metabolism and thermodynamics of muscle; (8) Kenneth Allan Caldwell Elliott, M.Sc.; subject: biological oxidations; (9) Margaret Honora Roscoe, B.Sc.; subject: the distribution and possible synthesis of vitamins B 1 and B 2.

THE HOUSING PROBLEM.

DEPUTATION TO THE MINISTER OF HEALTH.

THE Minister of Health, the Right Hon. Arthur Greenwood, M.P., received, on July 22nd, a deputation from the National Housing and Town-Planning Council, which put before him the following points:

1. That the Government should adopt a definite national programme for the building of 1,500,000 working-class dwellings with State assistance during the next ten years.

2. That all housing authorities should now be required to undertake a comprehensive and detailed housing survey of their respective areas.

3. That housing standards should be fully maintained and, in particular, that no three-bedroomed house built with State assistance should have a combined floor area of less than 760 square feet.

4. That the subsidy under the Housing Act of 1924 should be stabilized for a reasonable period of time, and that additional financial assistance should be provided to enable poor families with many dependants to occupy healthy dwellings.

5. That the Exchequer grant in aid of slum clearance schemes should be increased from one-half to at least two-thirds of the estimated annual loss on the schemes.

6. That the Town Planning Act should be extended so that it may apply to all land whether built upon or not, and that the existing powers for zoning should be extended.

The Minister's Reply.

The Minister, in reply, said that his frame of mind on housing generally was the same as in 1924. On the particular points put to him by the deputation he said that the 1924 Act recognized that there might be legitimate reasons for revision of the subsidy from time to time. He himself felt that it was impossible to commit Parliament for ten years, and any attempt to do so could be reversed by subsequent legislation. He could, however, say that he hoped to continue whatever subsidy was reasonable in the circumstances from time to time, and meanwhile had taken steps to preserve the Wheatley subsidy at its present figure until the next statutory review was due. This figure included the special provision made in the 1924 Act for rural areas. He doubted whether a general survey was desirable, but he thought that local authorities did keep a grip on the needs of their areas, and that they could be relied upon to keep abreast of changes in local circumstances. He agreed that accurate knowledge was necessary, but it ought not to be obtained in such a way as to divert the attention of local authorities from the actual provision of houses. He trusted that it would be possible in the next census to obtain better statistics than hitherto in regard to housing. He agreed that housing standards ought to be fully maintained, but he felt that in many areas there might be a real need for houses smaller than the three-bedroomed type for old couples and small families. While the main need was for three-bedroomed houses, he thought that local authorities should not be debarred from providing smaller houses, and that they could be trusted not to provide them in excessive numbers.

In conclusion, Mr. Greenwood said that the slum problem was not a separate problem from the provision of new houses. The Government were committed in the King's Speech to slum legislation, which he hoped to be able to produce at an early date. Slums could not be dealt with merely as a problem of finance, important as that was, and he trusted in his legislation to be able to ease the local authorities' task by making the procedure more simple. He agreed that the slum problem was bound up with a number of town-planning considerations. While he must avoid overloading any bill he might introduce, he would, at the same time, recognize the town-planning considerations that inevitably arose.

Ireland.

Health Insurance Bill (Irish Free State).

THE text of the National Health Insurance Bill, introduced in the Dail a fortnight ago to give effect to the major recommendations of the Committee on National Health Insurance, has been published. The bill proposes to abolish the county insurance committees, and to transfer their functions to the county councils, and to provide funds for the county councils for the purpose. The general purpose of the measure is to codify the Insurance Acts, and to simplify and lessen the expense of their administration. The difficulties which hitherto have existed regarding insurable married women are being surmounted by giving an insured female on marriage a marriage benefit, and providing that if she desires to work after marriage she will be in the category of persons who have never been insured. The measure also abolishes the deposit contributors' fund, and authorizes the entrance of members of this fund to approved societies within a prescribed period. Another section provides that persons in insurable occupations hitherto exempt because of certain private means can no longer claim exemption after January 5th next.

Down County Mental Hospital.

Dr. M. J. Nolan, resident medical superintendent of the Down County Mental Hospital, Kirkpatrick, in his report for the year ending December 31st, 1928, draws attention to the fact that valuable time is often allowed to elapse before patients are brought under care. The delay, in his view, is to some extent due to the troublesome legal formalities which have to be complied with before a patient may be subjected to treatment, and he expresses the hope that in the coming session of the new Parliament time may be found for legislation on matters of such vital importance both to the community and to the individual sufferer. In discussing questions of treatment, Dr. Nolan states that at no time since the opening of the hospital—now some sixty years ago—has moral treatment been exercised so thoroughly for the benefit of the patients. He

attributes the advance to the special qualifications of the medical staff, who have a more definite grasp than heretofore of the problems underlying mental abnormality; to the training of a nursing staff capable of carrying out instructions and combating conditions arising from derangement; and to the better equipment of the hospital, whereby the surroundings have been made as comfortable as those of a well-regulated home, and facilities are present for the application of whatever treatment may be indicated in particular cases. Moral treatment, he points out, involves the inculcation of regular habits and the provision of suitable occupation. In Holland, where he had recently made a tour of the mental hospitals, he found practically every patient employed, though this desirable state of affairs demanded in some cases the establishment of a very large nursing staff, even in the ratio of one nurse to every three patients. Dr. Nolan pays a tribute to the work of the National Council for Mental Hygiene, a branch of which is in course of formation in Northern Ireland; he hopes when the branch is in full working order that popular and practical addresses on mental hygiene will be given in Belfast and other northern centres. Dr. N. C. Patrick, inspector of lunatics, Northern Ireland, in his memorandum of inspection, draws attention to the high standard of excellence which continues to be maintained in the Down County Mental Hospital.

Maryborough Mental Hospital.

At a recent meeting of the committee of Maryborough (Portlaoighise) Mental Hospital, Dr. P. Grace, medical superintendent, presented his annual report. The report stated that the number resident on December 31st, 1928, was 528 (males 304, females 224), being an increase of 26 over the number in 1927. The daily average resident during the year was 618 as against 489 for the previous year. Of the assigned causes of insanity heredity was the chief, 25 men and 20 women being classified under that heading; mental stress accounted for 11 admissions; 5 cases were classified under mental instability; 7 cases were associated with senile decay and the same number with puberty and adolescence. There were no zymotic diseases during the year, and the general health of the patients and staff had been satisfactory. Occupational therapy received much attention in the treatment of patients, about seventy being employed on the farm, in the workshop, laundry, and sewing room. In the latter department, under the supervision of the matron, excellent work continued to be done in rug-making, needlework, etc. At the recent exhibition of work held at Castletown nine prizes were secured by the mental hospital exhibits.

Tuberculosis in County Galway.

Evidence of the satisfactory progress which has been made in recent years in the campaign against tuberculosis in Galway is supplied by Dr. Bartly O'Beirne, tuberculosis officer for this county. In his annual report he gives the following statistical details. The number of new applicants for treatment was 375; of these, 68 were insured persons and 307 were not. Tuberculosis was found to be present in 209 of the non-insured, and in 67 of the insured patients, the total thus being 276. Pulmonary tuberculosis was present in 155 non-insured patients and in 60 of the insured. Non-pulmonary tuberculosis was found in 54 non-insured patients and 7 insured ones. One hundred patients were still under observation, of whom all except one were not insured. The number of patients under 15 years old who were suffering from pulmonary tuberculosis was 13, and from the non-pulmonary form 23; 19 children were being kept under observation. In Dr. O'Beirne's report last year he stated that, though the number seeking advice had increased, it was not to be inferred that tuberculosis was extending in the county; what was actually happening was that the educational propaganda was having good effect. He remarks that in 1912, when the tuberculosis scheme was started in the county, it was only with great difficulty that a patient with early tuberculosis could be persuaded to go away to a sanatorium. At the present time the position had been reversed, and the great drawback in the county is that there is not sufficient accommodation for the number of applicants anxious to receive treatment. Many factors have brought about this desirable advance, but Dr. O'Beirne thinks that unquestionably the sanatorium has been the principal one. Medical practitioners have given great help by notifying all cases coming under their notice. The infected home is thus known, and measures are taken to prevent recurrence of the disease in other members of the family. Disinfection of the houses and rooms has been a very important weapon in the anti-tuberculosis campaign. Though much has been done, Dr. O'Beirne adds, there is still plenty of room for improvement.

A County Health Scheme in Limerick.

At a recent meeting of the Limerick County Board of Health a discussion was held on the proposed appointment of a county medical officer of health, and particulars of the recoupment for school inspection and child welfare. Dr. O'Dea, Government department medical inspector, said that the salary for the county medical officer of health would be allocated under three headings—one portion in respect of his duties as chief school medical inspector, a second portion for those of chief tuberculosis officer in the county, and the third portion for those of county medical officer of health. The sum allotted as chief medical officer of health was not recoupable, except in so far as allowed by the Public Health Act, 1878. Regarding the question of assistance, Dr. O'Dea said that with respect to school medical inspection the county would be divided into two; 50 per cent. was recoupable for assistants. The adoption of the scheme would not interfere with the position of the present county tuberculosis officer, but his duties might be altered. The speaker added that 50 per cent. was also recoupable in regard to nurses, and in the case of all other expenses that he knew of, such as travelling, printing, and stationery, 50 per cent. would also be refunded. The chairman estimated the annual cost of the county health scheme at £2,000. A resolution put to the meeting, that the county council be recommended to adopt the scheme, was carried by a very narrow majority.

England and Wales.

The British Social Hygiene Council.

THE annual general meeting of the British Social Hygiene Council was held on July 12th, when the Marquess of Linlithgow, the president, gave an address from the chair. Surveying the position since 1918, since which time the Council had received financial aid from the Government for specified purposes in connexion with propaganda against venereal diseases, the president said that the first thing to be noticed was the complete change in public opinion which had taken place. Before the agitation for the appointment of the Royal Commission the press of this country would publish nothing at all on the subject of venereal diseases. Now there was not much more difficulty in getting the subject of venereal diseases into the daily press than in getting any other serious subject into its columns. The Council, Lord Linlithgow continued, had undoubtedly done its share towards the reduction in the incidence of venereal diseases, but it was always difficult to assess the result of propaganda. Through direct lectures some six millions of the population had been reached during and since the war (excluding the men in the services). Written information had been sent to 112,000 persons on request as to facilities for treatment. He cited the case of two areas, each comprising a population of something over a quarter of a million, in one of which no active interest had been taken in venereal diseases propaganda, while in the other a regular campaign had been organized and an efficient scheme put into operation. In the former, in the most recent year, the new cases visiting the centres numbered 141, the non-venereal cases 11, and the number of attendances divided by new cases was 15.85. In the other area, in which there had been propaganda, the new cases visiting the centres numbered 171, the non-venereal

117, and the attendances divided by new cases were 33.1. Turning to the programme for the immediate future, Lord Linlithgow said that the first item was to endeavour to bring women infected with gonorrhœa under treatment. There was a large field awaiting the Council for work in connexion with the quicker recognition of gonorrhœa in women. The proportion of women suffering from gonorrhœa brought under treatment was less than it should be. The second item was to secure some adequate provision for the young mental defective and the borderline case. The third was to increase the measures of protective education and enlightenment among young people; and the fourth to secure the general approval of venereal diseases schemes supported by continuous propaganda throughout the country. The Council would continue to press for the appointment of whole-time or part-time social workers attached to the treatment centres, for following up non-attending patients and trying to secure the attendance of contacts. Under the provisions of the new Local Government Act the Council would be dependent upon contributions made by county and county borough local authorities to replace the central grant hitherto received from the Ministry of Health, and in view of the fact that the propaganda with which the Council was concerned was not a popular subject, some misgivings were felt as to its future financial resources. The difficulties had, however, been brought prominently before the Government and local authorities, and the president read a sympathetic letter from the new Minister of Health (Mr. Arthur Greenwood), expressing full agreement with the view that there were certain kinds of propaganda which could be most effectively directed by a voluntary body, such as the British Social Hygiene Council. Lord Linlithgow said also that the Council was much indebted to several medical bodies which had warmly endorsed the value of its work, and especially to the British Medical Association, which, in a letter issued to those of its members who were serving on public bodies, had stressed the great desirability of the Council obtaining an adequate measure of support from local authorities.

The Council has arranged a summer school, which is being held at the Westminster College, Cambridge, from July 25th to August 1st. Professor F. A. E. Crew will deliver a course of six lectures on biology and human affairs, and Professor P. S. Lelean five lectures on public health and social hygiene. Dr. Letitia Fairfield will discuss the report of the Mental Deficiency Committee, and other speakers include Dr. I. Feldman and Sir Basil Blackett. A course in evolutionary biology, with special reference to the work in school classes, will be given under the supervision of Dr. E. Watkin, at the West Riding of Yorkshire Education's Committee summer school at Bingley from July 31st to August 14th. Further particulars may be obtained from the secretary of the British Social Hygiene Council, Carteret House, S.W.1.

Mental Disease Research in Birmingham.

During the past year the work of the laboratory of the Joint Board of Research for Mental Diseases of the City and University of Birmingham, under the direction of Dr. F. A. Pickworth, has continued to centre round chronic infections of nasal sinuses and the intestinal tract. The relation of these infections to local lesions of the nervous system and disturbance of endocrine imbalance has been investigated bacteriologically, histologically, and chemically. The histological studies have involved careful sectioning and examination of post-mortem sinus material; the chemical studies have included basal metabolism determinations during sleep and, in the diagnosis of low-grade meningitis, estimation of the chloride content of the cerebro-spinal fluid. In 328 bacteriological examinations of urine and faeces two typical and one atypical dysentery Y organisms were recovered; on fifteen occasions were found Salmonella organisms differing only in agglutinative reaction or some other minor way from pathogenic paratyphoid organisms. Friedländer's bacillus has occurred twenty-nine times, and *B. faecalis alcaligenes*, *B. alkalescens*, and *B. proteus* each four times. Of 549 new admissions, 112—that is, 20.4 per cent.—gave positive agglutination reactions to the paratyphoid group; since it has been shown that the agglutination titre disappears far more rapidly in mental hospital patients than in normal subjects, these figures may be taken as evidence of the importance of gastro-intestinal infection in the etiology of mental disease. Of 760 sinus specimens taken from 73 patients, 103 contained staphylococci, 52 Hoffmann's bacillus, 37 organisms of the intestinal group, and 73 streptococci. Histologically, about half of the sphenoidal sinuses examined post mortem showed gross macroscopic inflammatory changes of the mucosa; a number also showed gross changes of the pituitary gland. To follow the results of treatment and estimate changes in the permeability of the brain membranes, 124 specimens of cerebro-spinal fluid have been examined cytologically, experiments being now in progress to detect areas of pathological change by injecting dyes into the cerebro-spinal system. By a modification of existing methods of estimating the chloride content of cerebro-spinal fluid, a technique requiring the use of only 0.15 c.cm. of fluid has been evolved, so far forty specimens having been examined. The normal chloride content of cerebro-spinal fluid is 725 to 750 mg. per 100 c.cm.; the average found in this investigation was 718 mg. It is held that this finding corroborates the theoretical consideration on which the research was undertaken—namely, that a low-grade meningitis is common in mental hospital patients.

Extension of Royal Victoria Infirmary, Newcastle.

In the previous annual report of the Royal Victoria Infirmary, Newcastle-on-Tyne, the house committee referred to the pressing need for further bed accommodation for staff and patients, and now in the recently issued report for the year ending December, 1928, some progress can be recorded in the attempt to deal with this. The committee's deliberations have largely centred round the question of how to use most effectively the Infirmary extension vacated by the Ministry of Pensions on the expiration of their lease on September 3rd, 1928; the most prominent point in this connexion has been the financial aspect of any suggested project of building extension or alteration, and the liabilities that might consequently be incurred for maintenance. The medical staff urged the desirability of providing a number of beds for paying patients; but while no definite decision has yet been reached, the committee considered it advisable to meet the apparently more urgent need of providing increased accommodation for the nursing staff, and has decided to extend the existing nurses' home by the addition of 150 bedrooms, since at present nearly 100 nurses are sleeping in other quarters. It is anticipated that the excess number provided for in the new extension will meet the requirements of the hospital when additional beds for patients are brought into use. The medical staff has urgently represented that part of the Infirmary extension should be set aside for paying beds, holding that such a measure would not only afford a solution of many difficulties which have faced the committee, but would impose no further financial liability upon the institution. The provision of such accommodation, it is claimed, would meet the special needs of certain classes of the community at present occupying the general beds of the Infirmary.

Beds for Paying Patients at Voluntary Hospitals.

A pamphlet[1] has been issued by King Edward's Hospital Fund for London containing a complete list of pay beds at the voluntary hospitals in London making returns to the King's Fund. When in 1928 the special committee appointed by the Prince of Wales, President of the Fund, to inquire into the subject of hospital accommodation for those prepared to pay more than ordinary voluntary hospital patients published its report[2] there were 1,055 pay beds at eighty voluntary hospitals in London. In May, 1929, the number had increased to 1,154 at eighty-eight hospitals, and particulars of these are embodied in the pamphlet under review. In an introduction attention is drawn to some of the salient matters in the Pay Beds Committee's report. The committee found that, exclusive

[1] London: Published for King Edward's Hospital Fund by George Barber and Son, Ltd., Furnival Street, E.C.4. 6d. post free.
[2] Report of the Pay Beds Committee of King Edward's Hospital Fund for London, July, 1928. London: George Barber and Son, Ltd., Furnival Street, E.C.4. Part I, 1s.; post free, 1s. 5d.

of certain extras and of medical and surgical fees, the charges for pay beds were usually round about four to six guineas a week, though at either end of the scale there were beds for the well-to-do and some for those in straitened circumstances. The committee concluded its report by expressing the following opinion.

"We consider that the existing provision of 1,055 pay beds has proved to be a very valuable addition to the voluntary hospital service of London; that a material extension of this provision is urgently required to meet the existing demand; and that the organization of a mutual insurance scheme to assist persons of moderate means to meet the cost of maintenance and medical fees is strongly to be recommended. We believe that an extension of the pay bed system at the voluntary hospitals, with due safeguards for the maintenance and extension of the ordinary beds, would be of advantage to the patients of all classes, to the individual hospitals, and to the voluntary hospital system as a whole."

In discussing an insurance scheme for the professional and middle classes the committee concluded that as it was desirable for as many prospective pay bed patients as possible to be in a position to pay full cost of maintenance in a pay ward and a medical fee as well, an effective mutual insurance scheme should be organized for assisting them to make provision in advance. Similar schemes already in existence, it pointed out, were those organized for ordinary hospital patients by the Hospital Saving Association and, for middle-class patients, by the British Provident Association. The committee held that, as far as London is concerned, an insurance scheme should be organized by a central body working in co-operation with the individual hospitals with pay beds, and concluded with the suggestion that the raising of a large capital sum for the provision and equipment of such beds for the use of those who cannot afford more than the cost of maintenance would be a form of assistance to the voluntary hospitals which might be commended to possible donors. In the pamphlet under review hospitals with pay beds are classified as follows: (1) general hospitals with schools; (2) general hospitals with resident medical officers; (3) general and cottage hospitals without resident medical officers; (4) hospitals for women; and (5) other special hospitals. Further particulars relating to the pay beds, including procedure as regards medical attendance and medical fees, are summarized in the report of the Pay Beds Committee. For detailed information about a particular hospital application should be made to its secretary.

The London Lock Hospital and Home.

In February last year, at the request of the board of management of the London Lock Hospital and Home, the late Minister of Health appointed a committee to inquire into the management, administration, and staffing of the institution, with special reference to the arrangements for the medical treatment of the patients, and the provision made for the moral, social, and material welfare of the inmates. The members of the committee were: the Right Hon. Sir John Eldon Bankes, chairman; Dr. John Fawcett; and Mrs. H. J. Tennant. During last December the committee submitted two reports, signed respectively by Sir John Eldon Bankes and Dr. Fawcett, and by Mrs. Tennant. The findings were communicated to the hospital towards the end of last January, and on July 11th the board furnished particulars of the action taken and said it contemplated giving effect to the recommendations of the committee. This letter, together with the committee's conclusions and recommendations, has now been published by H.M. Stationery Office (Cmd. 3363, price 3d.). In the letter from the board of the hospital to the present Minister of Health it is pointed out that, although only six months have been available to consider the recommendations, several of them have already been adopted and the rest are under active consideration. The laws of the hospital have been drastically revised, and the new ones, which were finally approved at the beginning of June, provide for a new and enlarged board of management, which shall include women to the extent of at least one-third. Under these new laws a house committee is being established to deal with the internal domestic management of the institution; this committee will be responsible for general supervision, and will arrange for constant and regular visitation. A finance committee has also been set up, and plans have been prepared for enlarging the out-patient department at the male hospital. Various domestic changes have been made, as the result of which the matron now attends all meetings of the board; the position and duties of the various registrars have been clearly defined; a female honorary surgeon has been elected with the same standing as a male honorary surgeon; the nursing staff has been increased, though it is admittedly not yet wholly adequate; and a teacher is to be appointed by the London County Council for the children's ward. The new board of the hospital has now come into existence and will take into consideration the advisability of reintroducing the training of pupil midwives; the nursing arrangements in the male hospital; the condition and improvement of the buildings; and the appointment of a whole-time trained social service worker. It is added in the letter that, as an act of grace, it has been decided to offer a monetary payment to the three former members of the staff who were dismissed in circumstances which have been reviewed by the committee of inquiry.

Sir William Hodgson.

Sir William Hodgson of Crewe, who has been for the last three years chairman of the Mental Hospitals Association, was the recipient of a cordial vote of thanks from the executive committee at the annual meeting of the association, which was held on July 17th, at the Guildhall. The value of his services was strongly emphasized, and great gratitude was expressed not only in respect of what he had done to advance the importance and prestige of the association, but also as regards his energetic and successful efforts to secure co-operation between this body, the County Councils Association, and the various other organizations which were concerned in the work of mental hospitals. Sir William Hodgson, who delivered an address, remarked that now that he had spent fifty years in the public service he thought the time had come for him to recognize the limitations of age. He hoped that certain of the very urgent questions relating to lunacy and mental deficiency would be realized as being outside the scope of party politics, and that a bill might be forthcoming without undue delay which would go far to meet some of the most acutely felt needs. He suggested that an early conference of representatives of local authorities should be called to consider the drafting of such a bill; it would undoubtedly meet with general support if it was constructed on enabling rather than compulsory lines, and tended to protect local government from undue arbitrary interference. Sir William Hodgson, who was mayor of Crewe in 1893, received his medical education at St. Thomas's Hospital, and has always shown a very active interest in the administrative side of mental medicine, and taken prominent part in local government in the county of Cheshire.

Victoria Hospital for Children, Chelsea.

Repeated outbreaks of infection, together with renovations of two wards during the past year, caused the average daily resident number of patients at the Victoria Hospital for Children, Tite Street, Chelsea, to drop from 105.25 in 1927 to 94.17 in 1928. While the pressure upon medical in-patient beds remained severe, the demand lessened on the surgical side, except for accommodation for tonsil and adenoid cases. In the annual report of this institution for 1928 this fall is attributed to the work of the welfare centres and the medical supervision of school children, which have reduced the need for major surgery in children, as compared with the position of ten or twenty years ago. Of the 3,419 cases treated in the tonsil ward, which was in constant occupation throughout the year, 389 were cases received in consequence of an agreement with the London County Council for treating recommended school children. It is mentioned in the report that this co-operation of the hospital with the council has proved to be most satisfactory and of great public utility. Operations in the out-patient theatre numbered 9,276, and there were 11,645 new cases in the out-patient department. The number of operations in the in-patient theatres was 409, as compared with 573 in the previous year.

Belgium.

[FROM AN OCCASIONAL CORRESPONDENT.]

Psychological Research in Industry.

THERE has come into existence in Belgium a research laboratory and registration bureau whose aims are to assist employers in all branches of industry in choosing new members of all grades for their staffs; to undertake research on matters of practical interest, either for individuals or for industries and commercial organizations; and to instruct students in psychological investigations, qualifying them to carry on practical work under the guidance of the laboratory staff. A new publication, *The Review of the Science of Labour*, has also appeared, with the subtitle *Psychological Technique, Organization*. Its scope includes general psychology; the physiology concerned in work; and psychological technique from the professional standpoint, or affecting the selection of workmen, or required in the scientific organization of industry. It deals, in short, with all those questions at issue in the leading industrial countries, most of which have such special journals of their own.

A Belgian Hospital Association.

For some time past those responsible for the organization, establishment, and administration of hospitals have been complaining that their work has not been adequately co-ordinated, and have asked for the creation of a central body to collect and record information, arrange meetings for discussions, and publish a periodical bulletin. The need has now been met by the formation of a Belgian Hospital Association, the functions of which have been defined after several meetings of a committee which included medical members of the hospital staffs, presidents and members of the Commission de l'Assistance Publique et de l'Hygiene, hospital and clinic superintendents, and representatives of the Red Cross. The work of the association comes within four categories: legislation; hospital administration and organization; hygiene; and architecture. The association comprises active members (representing public and private medical and charitable institutions), and also honorary members such as the presidents, directors, and administrators of hospitals and kindred organizations.

A Medical Course for Marine Officers.

The Lloyd Royal Belgian Society of Antwerp has just issued instructions that medical officers on some of its ships shall give, during voyages, a certain amount of medical instruction to the deck engineers and officers, with a view to teaching them enough about the signs and symptoms of various diseases to enable them, when necessary, to transmit accurate medical reports by wireless, and thereafter efficiently to apply any prescribed treatment. To ensure that all the higher ranks have been thus instructed, whenever they have to travel without a doctor, the company has arranged for these officers to serve in turn on boats to which medical officers are attached. These decisions have been taken on the initiative of the Marine Department of the Belgian Government, and are in accordance with the recommendations adopted at the Antwerp Medico-Radiological Conference.

Experiments on Animals.

The antivivisection campaign started some years ago in Belgium has culminated in the adoption by the legislature of the following proposal for the protection of animals: "Vivisection experiments carried out for the purpose of research or demonstration shall take place only in university laboratories, or in laboratories of similar status, under the control of the responsible director, and, with prescribed exceptions, only on anaesthetized animals." Approval of such laboratories will be conferred by royal decree.

Sanitary Brigades in the Belgian Congo.

In accordance with the request of the Belgian Colonial Association, steps have been taken for the formation of sanitary brigades entrusted with the special duty of dealing promptly with the primary sources of yellow fever. The Governor-General has ordered the establishment in all the chief outlying stations of a special supervisory control of sanitary services, and in the chief towns the reorganization of permanent sanitary brigades under the charge of an engineer or surveyor, and including a certain number of inspectors, sanitary officers, and native assistants.

First Aid in Industrial Accidents.

An exhibition dealing with accidents in the various industries has been organized at Liège for the purpose of giving instruction as regards their prevention. A large hall has been set apart for education in prevention and in first aid, which, when rightly applied immediately after the injury has occurred, obviates the risk of long incapacitation and grave sequels. Another hall has been devoted to electricity and the many essential precautions in this respect. In stands are illustrated the dangers arising from mismanagement of personnel and of machinery.

Correspondence.

A PHYSIOLOGICAL STUDY OF ASTHMA.

SIR,—The paper by the late Professor Brody and Professor W. E. Dixon, published in 1903, was, and still remains, so valuable that your recent abstract on July 13th (p. 68) will render good service to those who endeavour to solve the problem of asthma. Nevertheless I hold that, in one respect, these workers failed to reach the true clinical explanation of their brilliant researches, and which Dr. Harry Campbell (July 20th, p. 121) equally misinterprets—namely, the phenomena associated with the asthmatic paroxysm. I venture to recall my article on bronchitis in the *Encyclopaedia Medica* (Vol. II, 1899, p. 117):

"It is not improbable that, like the alae nasi and vocal cords, the bronchial muscle may rhythmically dilate and contract with inspiration and expiration. I believe that this largely explains why in bronchitis and asthma the dyspnoea is expiratory rather than inspiratory, inasmuch as the muscular spasm is more or less inhibited during inspiration, permitting air to be inspired more freely than during the period of bronchial spasm it can be expired, consequently the lungs become distended and emphysematous."

The asthmatic paroxysm is merely an exaggeration of the physiological bronchiolar dilatation on inspiration and contraction on expiration. The result is that the excessive bronchial contraction during expiration prevents the patient expelling as much as he had just inspired, before being compelled "to take a fresh breath," and with each succeeding inspiration and expiration more and more air becomes "locked in."

Gradually these short, quick, unhampered inspirations and prolonged hampered expirations cause so much retention of air that the lungs and chest walls are expanded to their utmost capacity, and then the patient has to struggle hard to get air inspired into the persistently overfilled lung—not because inspiration is hampered, but because there is no more room for the air to enter, owing to expiration being so obstructed that no effort can overcome the obstruction. But the over-activity of respiratory centres can be overcome by an anaesthetic or morphine, and almost at once the "lock gates" become normally open in expiration.

The collapsed lung of the newborn baby is physiologically expanded by precisely the same rhythmical dilatation and contraction of the bronchioles, for if the air inspired escaped as freely as it entered, the baby's tidal respirations would never distend the alveoli. In the newborn the distension goes on till a physiological balance is reached. In later life some over-expansion occurs with exercise—for example, in running, the increased air tension probably increases the *rate* of oxygenation of the blood. In the asthmatic, running often brings on asthma because the respiratory centres exaggerate this expiratory contraction phase.—I am, etc.,

Clifton, Bristol, July 20th. PATRICK WATSON-WILLIAMS.

THE TREATMENT OF PLACENTA PRAEVIA.

SIR,—Certain references which have appeared in the *Journal* from time to time to a letter of mine published in your issue of August 1st, 1925 (p. 230), on the treatment of placenta praevia, seem to make it advisable that I should restate my attitude on this important matter.

The fact that, within the last few years, ante-natal care has become more general makes it necessary to distinguish clearly between the condition placenta praevia and its consequent unavoidable haemorrhage. Before ante-natal care was widely adopted it was extremely rare for the existence of a placenta praevia to be recognized until unavoidable haemorrhage had occurred, and, consequently, our treatment was the treatment of the haemorrhage rather than of the placental malplacement. Now, on the contrary, many cases of placenta praevia are diagnosed before unavoidable haemorrhage has occurred—that is to say, at a stage when our treatment of the haemorrhage is prophylactic rather than active.

Accordingly, I would like to modify the views I expressed in 1925 in the following direction. If the existence of placenta praevia is recognized before serious bleeding has occurred, and after the child has become viable, then I think Caesarean section is justifiable, both with the object of saving the life of the child and of slightly improving the prognosis of the labour. Similarly, if the condition is recognized before the child is viable, and if it is possible to keep the woman under most careful supervision, so that, should bleeding occur, treatment can be adopted at any moment, I think again Caesarean section is justifiable as soon as the child has become viable. Naturally, the longer it is possible to wait the better.

If, on the other hand, unavoidable haemorrhage has occurred, and the woman is suffering from its effects, then I have still to learn that there is any treatment more efficacious than the classical treatment which I outlined in my previous letter. I would like, however, to add to what I then said: that I feel sure that Willett's forceps will often be found to provide a satisfactory substitute to bipolar version in cases of central placenta praevia.—I am, etc.,

Christchurch, N.Z., June 10th. HENRY JELLETT.

PERFORATION FOR THE SECOND TIME OF A GASTRIC ULCER IN AN OCTOGENARIAN.

SIR,—Mr. J. Price's case of perforation in a patient aged 70 (*British Medical Journal*, July 20th, p. 100) calls to my mind a man whose history from a surgical point of view is interesting. I will give the details as briefly as possible.

On April 1st, 1903, I removed three phosphatic stones from his bladder by the suprapubic route. He was then aged 67 years. On May 30th, 1911, I removed his prostate. He made a good recovery from both these operations. A very reserved man, he said very little about himself, but he admitted on interrogation that he occasionally suffered from dyspepsia. About a week before his first abdominal catastrophe he consulted his medical attendant for dyspeptic symptoms and pain in the epigastrium, which he said had no fixed relation to the taking of food.

On December 16th, 1919, the patient being now 78 years of age, he was seized with a sudden severe pain in the epigastrium, and became cold, clammy, and blue, with dilated pupils and rigid abdomen. I opened his abdomen about five hours after the first onset of pain, and found a perforation about the diameter of an ordinary lead pencil situated in an indurated area on the anterior surface of the stomach, towards the pyloric end and near the lesser curvature. The perforation was closed with linen thread sutures, and a portion of the great omentum was brought up and sutured to the damaged area. The abdomen was closed without drainage. The patient made a good recovery, and left the nursing home in three weeks. I saw him from time to time, and on inquiry he always said he felt quite well. At any rate, he made no complaint of his stomach.

At the age of 81, on September 9th, 1922, nearly three years after his last operation, he was again seized with a sudden severe pain in his epigastric region, with a rigid abdomen and collapse. Two and a half hours after the onset of symptoms I again opened his abdomen, and found a ragged opening over the site of the previous operation on his stomach. Owing to adhesions the operation was very difficult. The walls of the stomach were of almost cartilaginous hardness from an inch or so round the perforation, and the liver, omentum, and stomach were so closely adherent that great difficulty was found in closing the opening. Some of the indurated area had to be removed to allow of approximation of the margins of the perforation. Finally, by bringing down the edge of the liver and using any available portions of omentum in the neighbourhood, the opening in the stomach was occluded. Catgut sutures only were used on this occasion. The abdomen, after mopping out extravasated stomach contents, was again closed without drainage. The patient left the home about three weeks after his operation. Six months later he died suddenly of cardiac failure.

Recovery after operations for perforation of a gastric ulcer on two occasions, between the ages of 78 and 81 years, must be unique.—I am, etc.,

ANDREW FULLERTON,
July 21st. Professor of Surgery, Queen's University, Belfast.

PERFORATION OF A GASTRIC ULCER IN A SEPTUAGENARIAN.

SIR,—I was interested to read Mr. J. Price's account of a successful operation on a septuagenarian for a perforated gastric ulcer in the *Journal* of July 20th (p. 100), for I have recently had a similar case under my care.

On June 8th last I was called to see a Mr. W, aged 72, at 6 a.m. At 2 a.m. he had had an attack of acute abdominal pain, which was followed by "coffee ground" vomiting. When I saw him he was suffering from a considerable degree of shock. He was cold and clammy, his pulse was rapid and feeble, and he had a subnormal temperature. The abdomen did not move on respiration, and there was general rigidity of the abdominal wall. After his removal to a nursing home and consultation with Mr. A. E. Webb-Johnson, a perforation of a gastric or duodenal ulcer was diagnosed. Operation was delayed for a few hours owing to the patient's collapsed condition. He was kept very warm, and his general condition improved. At 2 p.m., twelve hours after perforation, his temperature had risen to 99.6° F., and operation was performed. A large perforation was found on the anterior surface of the first part of the duodenum. The perforation was closed, and gastro-jejunostomy was performed. The abdominal cavity was drained for forty-eight hours. The patient made an excellent recovery, and left the nursing home three weeks later.

In this case there had been no previous history of gastric symptoms, and the patient had had no occasion to see a doctor for over twenty years.—I am, etc.,

London, W.C., July 22nd. R. F. BOLT.

PRIMARY AND SECONDARY VACCINATION.

SIR,—During a recent visit to the Infectious Diseases Hospital, Singapore, it was recalled to my notice that secondary vaccinations as a rule run quicker and milder courses, and have shorter periods of incubation, than primary vaccinations. Where a revaccination reaches its height as to eruption about the twelfth day, the period of incubation is about three days. Revaccination may run an unaltered course resembling in all respects a primary vaccination, showing that immunity has disappeared. In other cases, however, a papule will appear in as short a time as twenty-four hours. This is what is known as "reaction of immunity," and actually is immediate, though not apparent as a papule until twenty-four hours later. The papule grows in size for three or four days, never becomes a vesicle, consequently never a pustule, and fades away within two or three weeks. I saw this in revaccinations when I was medical officer in the Egyptian Quarantine Service at the Hedjaz Pilgrimage Camp at El Tor in the Sinai Peninsula in 1906. In New Zealand in 1908 we had so mild a vaccine that even in primary vaccinations it was almost impossible to get a definite papule, vesicle, or pustule. As a matter of fact it was necessary to import from Cairo a fresh strain of vaccine.

In some cases there is a distinct accelerated reaction, the papule appearing within thirty-six hours and developing more quickly than in primary cases; the reaction reaches its zenith at the end of the seventh day and then rapidly subsides. Accelerated reaction indicates partial protection. Modified vaccinal lesions are really an index of satisfactory protection, and should be recorded on all vaccination certificates. If the interval between the first and second vaccination is less than two years, revaccination generally gives an immediate reaction; between two and ten years, usually an accelerated reaction; after ten years, revaccination runs

the course of a primary vaccination, though possibly not quite so severe. Modified reactions are explained in terms of anaphylaxis, and indicate increased protection. It is claimed that persons should be released from quarantine the moment they show a modified reaction, and that immediate reaction indicates complete protection.

With regard to actual vaccination, my experience in 1913 in the Sydney epidemic was that the younger members of the profession and the lay people assisting did not understand how to vaccinate; I saw numerous instances where blood was drawn. The method of using an ordinary sterilized needle, then merely dropping the vaccine on the arm and scratching the skin in four places, is simple and effective. In Singapore I was shown an even simpler method, that of pricking the skin with the point of a needle previously dipped in vaccine. The sharp sterile needle is held between the fingers of the right hand, so that the needle is parallel to the skin and pointing to the operator's left. The needle point is then pressed into the drop of vaccine each time. The motion should be at right angles to the skin and the needle, and not in the direction of the needle. It is claimed that the elasticity of the skin will pull a *minute portion of the epidermis over the point of the needle* at each pressure, so that the virus is carried into the layer of epithelial cells. The area of punctures should never be greater than one-eighth of an inch in diameter, and never deep enough to bleed. Properly done it is claimed that the percentage of successful vaccinations equals that of the vertical scratch method. The advantages of this method are its mildness, painlessness, and rapidity. A control site is unnecessary, as evidence of trauma disappears in about twelve hours, before the immediate reaction appears, and as the excess of virus is wiped off immediately, no dressing is required.

As Voltaire says, it is never safe to foretell the future—there has never been any—yet, although neither a prophet nor the son of a prophet, I suggest that the chances favour the occurrence some day, possibly soon, of an outbreak of small-pox in Australia. Should this outbreak occur I trust we shall be prepared to meet it.—I am, etc.,

J. S. PURDY, M.D.,
Metropolitan Medical Officer of Health, Sydney.

Sydney, N.S.W., June 6th.

"HELIOTROPE CYANOSIS."

SIR,—To your issue of June 15th (p. 1070) Dr. J. S. Haldane contributes a brief article upon the colour of the blood in fatal cases of the influenza epidemic of 1918. He thinks it extremely probable that the peculiar blue or violet cyanosis—heliotrope perhaps best describes the discoloration—was due to methaemoglobin, and that the organism responsible for the fatal character of the epidemic was a nitrite-forming bacillus.

May I be permitted a somewhat belated observation on this subject? In company, doubtless, with many other clinicians and pathologists, my colleagues and I in the Aldershot command were deeply interested in the causation of this conspicuous discoloration with its traditional baleful significance. But our investigations failed to supply any evidence for the tempting explanation that methaemoglobin was responsible, although we accepted the term "anoxaemia" originally advanced, I believe, by Dr. Haldane in relation to gassed cases examined at the front.

In no case investigated were the absorption bands of methaemoglobin detected, nor was there evidence of the oxygen-carrying capacity of the blood being reduced when Haldane's potassium ferricyanide method was employed. I may quote four cases from a paper which is before me as I write.[1]

Oxygen per 100 c.cm. blood:	
Control case	18.5 c.cm.
Case 1	17.0 "
Case 2	20.5 "
Case 3	18.5 "
Case 4	18.0 "

I regret I have no note or vivid recollection of the colour of the blood post mortem.—I am, etc.,

London, W.1, July 20th. ADOLPHE ABRAHAMS.

RELATIONSHIP OF ALASTRIM (VARIOLA MINOR) TO SMALL-POX (VARIOLA MAJOR).

SIR,—I am sorry to find that I have hurt Dr. J. A. Graham's feelings. I can assure him that it was quite unintentional, but since he thinks my letter, published in your issue of May 18th, lacking in courtesy, I can only express my regret.

As regards Dr. E. G. Fenton (*Journal*, July 20th, p. 124) the quotation he gives from Professor MacBride certainly seems to suggest that his theory of an inherited immunity due to vaccination in previous generations cannot be ruled out *a priori* as an impossibility. The main objections to it, however, rest on the following apparently established facts: (1) Non-fatal variola minor has long existed (under the names of "alastrim," "amaas," "Kaffir-pox," etc.) amongst primitive and comparatively non-vaccinated races. (2) Variola minor shows no sign of increased virulence in Leicester and other unvaccinated towns. (3) Variola major, when imported into this country, shows no sign of reduced virulence.

Personally, I see no difficulty in the view that variola major and variola minor split off from one another by a mutation at some period in their history, and that each variety has since become fixed. Variola major because of its severity and ease of recognition is finding it difficult to survive in this country under the conditions of modern public health administration; whereas variola minor, lacking these attributes, finds it much easier to survive.—I am, etc.,

Leicester, July 21st. C. KILLICK MILLARD.

THE WINNIPEG MEETING.

SIR,—I am sure everyone wishes to make the Annual Meeting at Winnipeg next year an outstanding success, and that on both sides of the Atlantic there is a hope that a large and representative party will travel from the Home Country. The opportunity is one which can only occur once in the average professional lifetime. It is satisfactory to know that arrangements are already well in hand to make the visit memorable to all those who are fortunate enough to be able to undertake the journey.

There is only one fly in the ointment, and that is the expense; and this, I fear, will be the determining factor in deciding the majority whether or not they can attend. The Association has issued a very attractive folder giving details of three tours in connexion with the meeting, but the cheapest of these works out at £96, which means that considerably more will have to be spent before the member gets back home again. I am afraid that very many general practitioners will have to abandon the idea of going to Canada unless the expense can be reduced substantially below this figure. The shipping companies advertise trips to the United States for £38 return, while special concessions are made to large parties, such as groups of school teachers, and so on. A large party belonging to one of the Free Churches visited Canada in the early summer of this year, and their numbers were so great that one of the big transatlantic companies provided them with a special ship for the round voyage. I cannot believe that the cost to each member of a party such as this could work out at £100 or over.

Of recent years I fear that the dazzling vision of wonderful new offices and such-like displays of wealth have rather blinded Headquarters to the fact that far and away the majority of the members of the British Medical Association are in fact men of strictly limited means. It would be a pity if the rank and file are going to be denied the chance of helping to make the Winnipeg Meeting historic in the annals of the Association.—I am, etc.,

Bridlington, July 10th. C. J. GORDON TAYLOR.

PROPHYLAXIS OF POST-OPERATIVE THROMBOSIS.

SIR,—Considerable light is thrown on the causation of post-operative thrombosis by Dr. Howel Evans's description (*British Medical Journal*, January 26th, p. 154) of the changes he found in the blood of patients recently subjected to operation. He states that following the operation there is an increase in the platelet count, which begins to be

marked from the fourth to the sixth day, reaching a maximum by the tenth day and returning to normal within another ten days. The average increase for his series was 60 per cent., though following major operations the rise was up to 150 per cent. Hitherto it has been taught that disintegration of the platelets resulted in the production of the coagulating substance pro-thrombin. Such disintegration is dependent, however, on the presence of ionized calcium in the blood (*Lancet*, May 11th, p. 993). Apparently calcium takes a part in the process of coagulation, not only after the coagulating agent has been liberated from the platelets, but also in securing its liberation. The corollary would seem to be that no matter how much the platelet count may be increased, if the ionized blood calcium is kept at a minimum, and mostly in the protein-combined, inactive form, then the period during which there is a tendency to post-operative thrombosis—namely, the tenth to the twentieth day—could be tided over safely.

Post-operative acidosis is said to have the effect of increasing the serum calcium; if the blood is rendered more alkaline, the *p*H being altered from 7.4 to 7.8, ionization of calcium salt is reduced by 60 per cent. With increasing alkalinity of the blood, calcium changes from the ionized to the non-ionized protein-combined state, in which it is chemically and electrolytically inactive. To achieve such alkalinity I use sodium bicarbonate and the disodium hydrogen phosphate, the former acting as a buffer of plasma, but dealing with only 5 per cent. of acid, while the latter acts as a buffer for red blood corpuscles, and is able to deal with 25 per cent. of acids.

I am not suggesting that an inflamed intima could not of itself be a sufficient cause of post-operative thrombosis; I am merely proposing a possible biochemical explanation. The administration of alkalis during convalescence may hinder the sound healing of wounds, it having been shown that a *p*H to the acid side of normal favours rapid healing. It is for this reason that some give ammonium chloride with the object of producing acidosis.—I am, etc.,

R. CHALMERS, M.D., F.R.C.S.Ed.

Darlington, July 17th.

SUNLIGHT VERSUS DIET IN RICKETS.

SIR,—In rickets, as in osteomalacia, the light factor is far more important than the diet. I do not believe that a child ever has rickets whose whole body is exposed to sunlight, any more than osteomalacia ever occurs in the outdoor worker.

In Kashmir, where osteomalacia is very common among the purdah women, rickets is hardly ever seen because the children go out from infancy and are in the sunlight all day. Soon after birth they may be seen sitting astride the mother or father's hip with no clothing other than a cap. Later, when they can crawl or walk, a coin or charm on a string round the waist is full dress till the age of 3 or 4, when they wear a shirt cut nearly to the waist for fear of soiling, a longer shirt with sleeves being adopted with advancing years. When rickets is seen it is among the richer infants kept indoors and overclothed in European fashion The disease is common in Bombay and big towns, where narrow streets and houses eight stories high exist, because sunlight hardly reaches the ground in the narrow alleys and the children cannot go out so freely.

It is a matter of common observation in the East that light on the body of the child can supplement the miserable milk supply of a mother suffering from acute osteomalacia (presumably because vitamin D is formed in the infant's skin by sunlight). No doubt this is why the outdoor worker in India thrives and does hard work on a diet inadequate for the indoor-living European who is deprived of light. The Indian coolie is healthy and well because his simple vegetarian diet is supplemented by the sun. Vegetarians who are office workers should note this, since the expensive craving for meat and variety in diet, as seen among town dwellers and the over-civilized, is an effort to obtain the necessary vitamin D which they could make better and more cheaply by exposing their bodies to light.

Dr. Rollier, in his own person, demonstrates the adequacy of a vegetarian diet provided there is sunlight on the body.—I am, etc.,

London, W.2, July 13th. KATHLEEN VAUGHAN.

GAS-OXYGEN ANAESTHESIA.

SIR,—With reference to the teaching of anaesthetics, may I relate an incident which, though possibly quite exceptional, may, however, be of some significance? A few years ago I was discussing the anaesthetic for a particular case with a house-surgeon at a small hospital; he had qualified at one of the leading London schools, after which he had held an appointment at another small hospital, where, incidentally, a Boyle's apparatus was in use. I recommended gas and oxygen for this particular case, whereupon the house-surgeon looked at me in some surprise and said, "But can you give gas and oxygen unless you give an endotracheal?"—I am, etc.,

London, W.1, July 20th. R. J. CLAUSEN.

Obituary.

GEORGE ALLAN MALING, V.C., M.B., B.Ch.

WE regret to record the death of Dr. George A. Maling, on July 9th, at his residence in Lee, S.E.

George Allan Maling was the youngest son of Dr. E. A. Maling, J.P., of Blackwell Hall, Darlington. He was born at Sunderland, in October, 1888, and after leaving Uppingham School studied medicine at the University of Oxford and St. Thomas's Hospital. He graduated M.B., B.Ch.Oxon. in 1914, and in the following year took the diplomas M.R.C.S., L.R.C.P. He obtained a temporary commission in the R.A.M.C. in January, 1915, and five months later crossed to France, being attached to the 12th Battalion of the Rifle Brigade.

It was announced in the *London Gazette* of November 18th, 1915, that the Victoria Cross had been conferred on him "for most conspicuous bravery and devotion to duty during the heavy fighting near Fauquissart on September 25th, 1915. Lieutenant Maling worked incessantly with untiring energy from 6.15 a.m. on the 25th till 8 a.m. on the 26th, collecting and treating in the open under heavy shell fire more than 300 men. At about 11 a.m. on the 25th he was flung down and temporarily stunned by the bursting of a large high-explosive shell, which wounded his only assistant and killed several of his patients. A second shell soon after covered him and his instruments with debris, but his high courage and zeal never failed him, and he continued his gallant work single-handed."

Dr. Maling was also mentioned in dispatches and was promoted captain. He subsequently served for a short time at the Military Hospital, Grantham, and then returned to France for two years with the 34th Field Ambulance of the 11th Division.

After being demobilized at the end of the war he obtained the post of resident medical officer to the Victoria Hospital for Children, Chelsea. He subsequently commenced practice in Lee, and was appointed surgeon to out-patients at St. John's Hospital, Lewisham. In 1917 he married, and leaves a widow and one son.

Medico-Legal.

ALLEGED PROFESSIONAL NEGLIGENCE.

SHEWRY *v.* MAYBURY.

THE special jury having failed to agree upon a vital question which had been left to them to answer, the Lord Chief Justice, after consideration, held that it was not possible for him to enter judgement for either party in the action brought in the High Court of Justice by Leslie Eric Shewry, an infant suing by his father, Inspector Marcus Sidney Shewry of the Portsmouth Borough Police Force, for damages for injuries suffered through the alleged negligence of Dr. Lysander Maybury, a medical practitioner of Southsea. The case was fully reported in the *Journal* of June 29th (p. 1185).

It was alleged that in August, 1920, when the infant plaintiff was 14 days old, Dr. Maybury diagnosed him to be suffering from congenital syphilis, and injected a preparation known as "N.A.B." into the neighbourhood of the child's brain, with the result that he had convulsive fits and became an incurable mentally defective epileptic.

Dr. Maybury, whilst admitting having made five injections of "N.A.B." into the child's head, said that his treatment was in accordance with the best medical practice.

The special jury, in their answers to the questions left them by the Lord Chief Justice, found that Dr. Maybury believed that the child had congenital syphilis, but was negligent in diagnosing that he was suffering from that disease, and that the doctor was not negligent in deciding on the method of treatment, but that he was negligent in his general treatment. The jury, however, failed to agree on the first question: "Was the condition of this infant caused by the treatment administered by the defendant?" and stated that there was no prospect of agreement.

Counsel directed the Lord Chief Justice's attention to a provision in Order XXXVI, rule 39, of the Rules of the Supreme Court: that "the judge shall, at or after trial, direct judgement to be entered as he shall think right."

The Lord Chief Justice's Decision.

In his reserved judgement, Lord Hewart said there appeared to be no doubt that a judge who had ruled at the conclusion of the plaintiff's case that there was some evidence for the jury was nevertheless entitled at the conclusion of the whole case to reconsider his ruling and to enter judgement for the defendant if he was then of opinion that the plaintiff's evidence failed to disclose any cause of action against the defendant. This case went to the jury in the usual way, and the jury, having failed to agree on the first and fundamental question (though they agreed upon the remaining questions), were discharged. In these circumstances he was asked to consider whether there was a case to go to the jury. Having carefully examined the whole of the evidence, he had no doubt that, if it had been his duty to answer the question, "Was the condition of this infant caused by the treatment administered by the defendant?" he would have answered it in the defendant's favour. But a judge could not be placed in the position of the jury, and the very different question which he had now to decide was whether on the evidence it would have been right to direct the jury to find a verdict in the defendant's favour. In his opinion it would have been wrong so to direct them. There was some evidence, including some medical evidence, which, if the jury were prevailed on to accept it, was sufficient to entitle them to answer the question affirmatively. It might well be that, in view of the intrinsic value of that evidence, and of the contrast between it and the cogent evidence adduced on behalf of the defendant, such an answer would have excited legitimate surprise. But all such considerations appeared to him to be quite irrelevant if, in fact, there was a conflict of evidence for the jury to determine. Here, he thought, there was such a conflict, and the jury having disagreed it was not possible for him to enter judgement.

MEDICAL MAN ACQUITTED.

At the Birmingham Assizes, on July 16th, Dr. B. E. Acland of Hanley was charged with unlawfully using an instrument in February last with intent to procure the miscarriage of Elsie Hulme, aged 19; and Norman Birkett, brassfounder, was charged with aiding and abetting. The case had been transferred to Birmingham from the Staffordshire Assizes. Both defendants pleaded "Not guilty." After hearing the opening speech by Mr. St. John Micklethwaite, K.C., for the prosecution, and the evidence of the girl, Mr. Justice McCardie held that, on the evidence, there was no case for the jury, and at his direction the jury returned a verdict of "Not guilty." Both defendants were accordingly discharged.

POST-ENCEPHALITIC MORAL DEFECT.

At the Folkestone Quarter Sessions, on July 20th, before the Recorder, Mr. Roland Oliver, K.C., a man named Hills, aged 26, was charged with an offence against a young woman. The jury returned a verdict of "Guilty," the foreman stating that they regarded the prisoner as a *pest to society*. The chief constable informed the Recorder that there were fifteen convictions against Hills, most of them for assaults on women, and he had been deported from Canada after conviction for a similar offence. Dr. W. D. Higson, medical officer to H.M. Prison, Maidstone, stated that he had had Hills under observation since his remand. In his opinion the prisoner was a mental defective and certifiable under the Mental Deficiency Acts. It appeared that at the age of 16 Hills suffered from encephalitis lethargica, and as a sequel to that disease his morals and general behaviour had deteriorated. The Recorder announced that the prisoner had been certified as a moral imbecile, and that he was making an order for him to be sent to an institution without specifying any time for his detention. After the prisoner's removal the Recorder explained to the jury that under the new statute he had power to deal in this manner with a person in whom mental defect was coupled with strongly vicious or criminal propensities, and who needed care, supervision, and control for the protection of others.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a congregation held on July 20th the following medical degrees were conferred:

D.M.—F. J. Bach.
B.M.—J. C. Nicholson, W. J. Walter.

UNIVERSITY OF CAMBRIDGE.

At a special congregation held on July 20th the following medical degrees were conferred:

M.D.—E. A. B. Pritchard, W. R. F. Collis, R. A. McCance.
M.B., B.Chir.—*G. E. Lewis, F. R. McCay, C. L. Stote, C. E. Woodrow, R. W. Windle, D. M. Stern.
M.B.—P. B. Rittel.
B.Chir.—*S. Tyagaraja, F. Bush, C. P. Campion, F. W. J. Wood, C. J. Grouch.

* Admitted by proxy.

UNIVERSITY OF LONDON.

[illegible] University [illegible]sion to Sir [illegible] University Chair of Anatomy, tenable at St. Bartholomew's Hospital. From 1923 to 1927 he was Assistant Professor of Anatomy at University College, and since 1927 has been Professor of Anatomy in the University of Adelaide.

Dr. R. A. Young has been appointed the representative of the University at the conference of the National Association for the Prevention of Tuberculosis, to be held at Newcastle-on-Tyne in October.

Mr. H. L. Eason has been appointed a governor of Bedford College and Mr. H. J. Nightingale a governor of University College, Southampton.

The University Studentship in Physiology for 1929-30, value £100, and tenable in a physiological laboratory of the University, or of a school of the University, has been awarded to Miss Margaret Hill, B.Sc.

Dr. E. Graham Little, M.P., has been elected chairman of the Council for External Students.

The following candidates have been approved at the examinations indicated:

M.D.—*Branch I, Medicine*: A. R. Balmain, S. Berman, M. H. C. Dyson, L. I. Honzell, J. C. Hoyle (University Medal), R. H. Knight, Lucy M. T. Masterman, S. K. Montgomery, T. Robson, K. S. Smith, R. G. R. West, Katharine G. L. Williams. *Branch IV, Midwifery and Diseases of Women*: Elaine G. H. Barenger, Phyllis V. L. Epps, Dorothy E. Stewart. *Branch V, State Medicine*: W. E. Snell. *Branch VI, Tropical Medicine*: J. A. Carman.
M.S.—*Branch I, Surgery*: R. Brooke, H. I. Deitch, J. R. M. Whigham. *Branch IV, Oto-Rhino-Laryngology*: S. A. Beards, Mildred Wards (University Medal).

UNIVERSITY OF LEEDS.

MR. W. R. SPURRELL, F.R.C.S., has been appointed Research Assistant in the Department of Experimental Pathology and Cancer Research.

UNIVERSITY OF EDINBURGH.

A GRADUATION ceremonial took place in the McEwan Hall on July 17th, when the following medical degrees and diplomas were conferred:

M.D.—‡G. G. Allan, ‡H. M. Anderson, ‡J. M. Bassett, *G. L. Bord, E. H. Brindle, ‡W. R. D. Fairbairn, ‡G. B. Flint, Alice J. Gray, J. W. Hunter, *C. F. W. Illingworth, ‡J. B. King, S. Maevicar, R. [illegible] T. Moir, J. R. Murdoch, A. [illegible] Smith, Florence L. Telfer.
M.B., [illegible] *I. Alcock, D. M. Alston, L. [illegible] Bishop, ‡T. P. Bliss, W. J. Bra[illegible], J. A. P. Cameron, A. F. K. Cla[illegible]xley, T. Crowley, J. A. Cuthber[illegible] S. C. M. Downing, E. F. J. Dun[illegible] Fletcher, J. M. Fosbrooke, D. A. Fowler, D. Fraser, J. A. Gemmell, ‡W. H. Gillespie, K. Girsis, ‡E. L. Godfrey, G. Graham-Cumming, G. M. Greig, A. Haddow, R. Hardy, ‡R. Harkness, D. Harley, R. A. K. Harper, ‡C. F. Hay, Jean M. [illegible] D. K. L. [illegible] R. P. A. [illegible] Orchard, D. S. J. R. M. Rea ‡Agnes Y. Sa[illegible] Agnes D. Sloan B. Stein, W. [illegible] E. J. G. Walla[illegible] W. E. Willis, Jessie R. Wilson, J. F. A. Wood.

DIPLOMA IN RADIOLOGY.—G. C. Field, A. J. G. Mackay, M. J. S. Pillai, S. Singh, Elizabeth N. Thompson.

The following awards were presented:

[illegible] [illegible]nard [illegible] has [illegible]cular [illegible]rosy. [illegible] and [illegible] Gold Medal: J. Laurie.
Allan Fellow[illegible] [illegible]nd Clinical Surgery: G. P. Hay: Murchison Memorial Scholarship in Clinical Medicine:

J. G. W. Hill. M'Cosh Graduate's and Medical Bursaries: R. M'K. Honey. Mount Scholarship in the Practice of Physic: R. Harkness. Buchanan Scholarship in Midwifery and Gynæcology: J. Laurie. James Scott Scholarship in Midwifery and Hunter Prize in Anatomy and Surgery: E. L. Godfrey. Conan Doyle Prize: R. D. Aitken. Annandale Gold Medal in Clinical Surgery: R. F. Barbour. Murdoch Brown Silver Medal in Clinical Medicine: C. P. Hay. Royal Victoria Hospital Tuberculosis Trust Gold Medal: A. G. G. Melville. Scottish Association for Medical Education of Women Prize and Dorothy Gilfillan Memorial Prize: Agnes Y. Savage. Wightman Prize in Clinical Medicine: R. D. Aitken. Pattison Prize in Clinical Surgery: J. A. P. Cameron and R. A. T. Rouse (equal). Cunningham Memorial Medal and Prize in Anatomy: C. A. Green. Whiteside Bruce Bursary: A. Brown.

* Awarded go'd medal for thesis. ‡ Commended for thesis.
† Highly commended for thesis. ‖ Passed with honours.

At the conclusion of the graduation ceremony an address to the new graduates was delivered by Professor T. J. Mackie.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on July 16th, with the President, Dr. Robert A. Fleming, in the chair.

Drs. G. S. Brock (London), F. W. Woolmbe (Rhodesia), A. Rae Gilchrist (Edinburgh), and Rutherford Dow (Fife) were introduced and took their seats as Fellows of the College.

Drs. F. T. Bowerbank (New Zealand) and W. T. Munro (Kinross) were elected Fellows of the College.

It was announced that Dr. S. A. Kinnier Wilson (London) had been appointed Morison Lecturer for 1930.

NATIONAL UNIVERSITY OF IRELAND.

THE following medical degrees were conferred by Dr. Denis J. Coffey, Pro-Vice-Chancellor of the University, on July 13th:

M.D.—T. B. Gallagher.
M.Ch.—R. T. Cullen, W. D. O'Donoghue.
M.A.O.—A. W. Spain.
M.B., B.Ch., B.A.O.—W. P. O'Callaghan, D. Finn, T. J. P. Kerwick, J. T. Lavan, T. J. A. Carty, J. Hannigan, P. Hogan, M. J. Howlett, D. McCarthy, D. A. MacLaughlin, Susan MacMahon, Maureen V. Magee, J. A. A. Murray, P. J. Naglo, Florence O'Driscoll, J. J. Stuart.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

BEFORE Parliament rose, on July 26th, for the summer recess legislation was carried dealing with unemployment insurance, the housing subsidy, and other subjects. On several of these issues larger bills are to be introduced after the House reassembles in October. A bill is also promised dealing with the mining industry and hours of labour in coal mines. A preliminary outline of this was given in the House of Commons this week.

Pensions.

Answering Dr. Morgan, on July 18th, Mr. ROBERTS (Minister of Pensions) said that during the last period for which information was available 363 medical officers on an average were employed by the Ministry of Pensions on a sessional basis. Two-thirds were specialists. In the six months ended June 30th, 24,677 *final* awards were made, and about 380,000 pensioners now received final awards of life pensions. During the past two years 7,529 appeals were made to assessment appeal tribunals.

In reply to Mr. Ayles on July 18th, Mr. *Roberts said the* male nursing staff in institutions under his control dealing with mental and severe nervous disorder was required, to the utmost extent possible, to be experienced in handling such cases. Of 62 male nurses employed in nursing certified cases, 25 also had a certificate. Mr. AYLES asked whether Mr. Roberts would see that only certified male nurses were *employed* in State institutions. Mr. ROBERTS replied that he understood the Board of Control had not found it practicable or desirable to advise that standard in public mental hospitals.

Mr. MACLEAN asked, on July 18th, whether the Minister of Pensions had considered reorganizing the constitution of the appeal tribunals. Mr. BEN SMITH (Treasurer of the Household) replied that members of the pensions appeal tribunals were not appointed by the Minister of Pensions. Save for the reduction from time to time in the number of their members there was no intention of reorganizing their constitution.

Housing Bill.

In the House of Commons, *on* July 22nd, Mr. GREENWOOD moved the third reading of the Housing (Revision of Contributions) Bill. During the debate which followed, Mr. T. SNOWDEN regretted that Dr. Fremantle had, on a previous occasion, asserted that medical officers of health urged that the Treasury should reduce the sums which were spent by the late Government on housing in order to provide more money for other important health services which were calling out for treatment. He (Mr. Snowden) regretted that speech because if, as he believed, the subsidy would encourage housing, it would remove evils caused by bad houses and, in consequence, *reduce* possible expenditure on the other matters to which Dr. Fremantle had referred.

Dr. FREMANTLE: I only said that it was an extremely extravagant way of doing it.

Mr. SNOWDEN replied that it was better to spend money on housing than to have to spend it on building hospitals. He would like to think that Dr. Fremantle did not represent the views of other medical officers of health, or even of the medical profession. At any rate, it would not do for a medical officer in the West Riding of Yorkshire to adopt the views expressed by Dr. Fremantle in that House.

Miss RATHBONE, speaking as a member of the Liverpool Housing Committee, asked whether the subsidy would assist in the production of houses which would meet the needs of those who could not pay economic rents. The error in the past had been in the method of applying the subsidy. It should never have been used for a flat-rate reduction of rents. Certain authorities had adopted the plan of making a rebate off rent of 6d. for each child, balanced by 1s. on the rent for each lodger. The Government, while thinking out their slum clearance policy, should give every possible encouragement to local authorities to use their subsidies in the way she suggested.

Dr. VERNON DAVIES said the question the House had to decide was *whether* the subsidy really filtered down to benefit the tenant or merely went to builders and builders' merchants. His belief up to the present was that the late Minister of Health had been right in his attitude, and that the present Government were *making a grave mistake.*

The third reading was agreed to, and subsequently the bill received a first reading in the House of Lords.

The second reading of the bill was moved by Lord ARNOLD in the House of Lords on July 23rd. He said that the Government had received an assurance from a body representing the local authorities that, after the passage of the bill, their programmes would be continued without any hiatus. This bill was a temporary measure. The BISHOP OF SOUTHWARK said that the problem of slum clearance never would be tackled until new houses, at low rents, were built within reach of their occupants' work. If the problem was to be solved they would be driven back on the policy of giving special children's allowances for rent. The medical officer of health for Southwark had stated that in one year there were 10,000 occupied houses in Southwark which were not in a reasonably fit state for human habitation.

The Lords agreed to the second reading.

Small-pox.—Answering Mr. Beaumont, on July 18th, Mr. GREENWOOD said small-pox accommodation had been provided in every county with the exception of two in England and one in Wales. In these three counties arrangements had been made for the treatment of cases of small-pox in hospitals situated in adjoining counties. With modern means of transport there were advantages in providing small-pox hospitals to serve wide areas. Answering Mr. Harris on the same day, Mr *Greenwood* said there were occasional errors in diagnosis, and he could not say that no case of chicken-pox was included among the cases notified as small-pox.

Treatment of Physically Defective Children.—Mr. ADAMSON, replying to the Duchess of Atholl on July 16th, said that no education authority made independent provision for *major operative* treatment of physically defective children, such treatment being ordinarily carried out by the voluntary hospitals. Thirteen education authorities had approved arrangements for the treatment of deformities by massage and remedial exercises, and twenty-one authorities had approved arrangements for treatment by orthopaedic appliances. In practice, all education authorities supplied splints, surgical boots, and such-like appliances where necessary. There was no scheme for orthopaedic treatment *provided jointly* by an education authority and a maternity service and child welfare authority, though there were a number of cases in which there was co-operation between the two authorities in the use of premises.

Venereal Disease Clinics.—In a reply to Dr. Morgan, on July 18th, Mr. GREENWOOD said the Ministry of Health had approved 183 venereal disease clinics in England and Wales, of which 60 were administered directly by local authorities. During 1928 the number of new cases dealt with *at these* clinics was 65,903: of these, 27,597 were found not to be suffering from venereal disease, and the total number of attendances of patients was 2,422,749. Proposals for the provision of new clinics, or for the extension and improvement of the present facilities for treatment, were under consideration.

Workmen's Compensation.—In an answer, on July 18th, to Mr. Philip Oliver, who asked him to make an order extending the Workmen's Compensation Acts to cancer of the bladder affecting workers in aniline factories, Mr. CLYNES said it had not been definitely established that cancer of the bladder was caused by employment in aniline works. The matter was a subject for research by the London Cancer Hospital. He would see if the Home Office could facilitate this investigation.

London Lock Hospital.—On July 22nd Miss LAWRENCE told Mr. Knight that the Minister of Health had received a request from the National Council of Women and other societies for the publication of the report on the London Lock Hospital. The papers recently presented to Parliament gave particulars of the recommendations of the committee, and of the action taken and contemplated by the governing body of the hospital to give effect to them. This action had improved the administration of the hospital, and further improvements were in prospect. The best interest of the future of this voluntary hospital would not be served by reviving discussion of former unsatisfactory conditions which the governing body had altered or proposed to alter. It was accordingly not the Minister's intention to publish the *committee's* reports.

Phototherapy.—Mr. GREENWOOD, in reply to Mr. Harris on July 18th, said inquiries had been made during recent years by medical officers of the Ministry of Health into the application of phototherapy (including artificial light) to the treatment of disease. Results had been published in the annual reports of the chief medical officer. These observations were being continued, and he did not see any necessity for a further inquiry. The best results of this form of treatment had apparently been obtained in cases of rickets and of certain forms of non-pulmonary tuberculosis.

Raising of School Leaving Age.—Sir CHARLES TREVELYAN (Minister of Education) announced to the House of Commons on July 18th that the Government had decided to prepare legislation to raise the school age to 15 from April 1st, 1931. He would ask local education authorities and professional bodies to consult him on the proposal. He could not say whether legislation would be introduced in the present session of Parliament.

Opium Consumption in India.—On July 22nd Mr. BENN told Mr. Cecil Wilson that the committee appointed to examine the position in regard to opium in the Malwa States had reported, but no decisions had been taken. Four of the six inquiries into the consumption of opium in areas under five provincial Governments in India had been completed. As soon as the remaining two were finished the Government of India proposed to convene a conference to collate the results obtained before the local Governments passed Orders. The Bengal report had been published.

The Country's Water Supplies.—Mr. GREENWOOD, on July 22nd, told Mr. Ayles that a survey of potential water supplies of the country would involve a great amount of detailed investigation, and would by itself be of doubtful value. The most practical course was the formation of more advisory regional water committees on the lines advocated in the booklet issued by his department last October. By means of these committees not only the available supplies, but also the needs, of all the districts in the region could be ascertained and a definite policy recommended for meeting requirements over a long period. The findings of these committees could then be co-ordinated in the general interests and a national policy formulated.

Effect of Re-valuation on Hospitals.—Mr. GREENWOOD told Mr. Lee, on July 18th, that the Ministry of Health had received communications about the effect of the general re-valuation on hospitals and similar institutions, but he had no general information on how far the recommendations of the Central Valuation Committee with respect to the assessment of such hereditaments had been followed. The matter was not one in which he was empowered to interfere with the discretion of the local authorities, but it was open to any representative body to call the attention of the Central Valuation Committee to substantial departures from their recommendations and to submit suggestions on which, if necessary, more precise recommendations might be based.

Education of Blind, Deaf, and Mentally Defective Children.—Sir C. TREVELYAN told Dr. Morgan, on July 15th, that the cost (excluding loan charges) of educating a blind child was approximately £29 in a day school, and £88 in a residential school. The corresponding figures for the deaf were £43 and £82, and for the mentally defective £25 and £71. Dr. MORGAN asked whether part of this cost could be saved in future by a judicious health expenditure in infant years, and by the development and extension of infant welfare centres. Sir CHARLES said this raised issues with which it was difficult to deal in an answer to a question.

Pensions of Tuberculous Ex-service Men.—Answering General Wright, who suggested the stabilization of pensions of tuberculous ex-service men residing in a colony at Efford, near Plymouth, Mr. ROBERTS (Minister of Pensions) said it would not be in the interests of the men to make final awards to any particular group of men suffering from tuberculosis. Final awards were made in any cases found to be suitable. In other cases awards were made, wherever possible, for long periods to spare the pensioners frequent examinations.

Notes in Brief.

In the opinion of the Minister of Transport the provision of first-aid outfits on public vehicles is not a matter to be associated with the conditions attached to licences.

Legislation for amendment of the present law must precede ratification of the International Labour Office Convention of 1921 concerning the use of white lead in paint. The Home Secretary states that such legislation will be considered in connexion with the proposed Factories Bill.

On January 1st, 1929, there were 68 private institutions in England and Wales under the Lunacy Acts, with 4,619 patients therein. The discharges in 1928 were 742.

Not including feeble-minded children in the charge of the education authorities, there were in England and Wales on January 1st, 1929, 66,454 mental defectives recognized by local authorities, 19,138 being maintained in institutions.

Sir Charles Trevelyan is considering making provision for blind or crippled children who do not at present attend any schools. At the end of 1928 in England and Wales 602 blind and 5,336 crippled children were not attending any school. On the same date there were 3,935 totally deaf children of school age in England and Wales, of whom 3,464 were taught in special schools.

A reduction in the port establishment numbers of the chief and petty officers of the sick berth branch of the Royal Navy has been authorized, and vacancies in the Portsmouth Port Division have not been filled.

Medical News.

THE Fellowship of Medicine announces that from July 29th to August 24th a course in urology will be held at the All Saints' Hospital during the afternoons and evenings. A two weeks' course at the Queen's Hospital for Children, from August 12th to 21st, will consist of demonstration of cases rather than lectures. Luncheon and tea are provided by the hospital authorities. The courses in September will include diseases of the chest at the Brompton Hospital, from September 9th to 14th; diseases of infants at the Infants Hospital, from September 9th to 22nd; psychological medicine at the Bethlem Royal Hospital, from September 10th to October 5th; and medicine, surgery, and the specialties at the Westminster Hospital, from September 16th to 28th. The Fellowship has also made the following arrangements: a whole-day course in gastro-enterology at the Prince of Wales's Hospital, from September 30th to October 4th; a M.R.C.P. course comprising a series of sixteen lectures by well-known authorities, at 8.30 p.m., at the Medical Society of London, from October 15th to December 6th; and an all-day course comprising medicine, surgery, and the specialties at the Metropolitan Hospital, Kingsland Road, from October 21st to November 2nd. A general course consisting of the clinical practice of the hospitals associated with the Fellowship continues throughout the year, and may be begun on any day of any week. Comprehensive tickets are issued for varying periods from one week upwards to one year at fees ranging from £2 2s. to £21. Special arrangements are made for part-time work. Syllabuses of all courses and other information may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A SPECIAL two weeks' course in orthopaedics (lectures, demonstrations, operations, and the practice of the hospital) will be held at the Royal National Orthopaedic Hospital from November 18th to 30th; fee three guineas. Names of those wishing to attend should be sent to the secretary of the hospital, 234, Great Portland Street, W.1, or to the secretary, Fellowship of Medicine, 1, Wimpole Street, W.1, not later than November 12th.

AN address and a sum of money will be presented to Robert Hopkins, Bedell of the Medical School, St. Thomas's Hospital, from the past and present students at the annual dinner on October 4th, on entering his fiftieth year in the service of the Medical School.

AT a special meeting of the Section of Odontology of the Royal Society of Medicine held on July 17th a bust of the late Dr. J. Howard Mummery was unveiled and presented to Professor A. D. Black, of the Dental Faculty of the North-western University, Chicago, by its London *alumni*. The American Ambassador was present at the ceremony. Professor Black, who received the bust on behalf of the North-western University, said that it was because of his high regard for the scientific achievements of John Howard Mummery that he had journeyed to London for this occasion.

A CIVIL LIST pension of £50 has been granted to Mrs. Elizabeth Mottram Williams in recognition of the services of her husband, the late George Chisholm Waldemar Williams, in connexion with the application of Roentgen rays to the treatment of disease. Mr. Waldemar Williams died on April 10th, 1928, and an obituary notice appeared in our issue of April 21st of that year.

THE Metropolitan Asylums Board have appointed E. W. Todd, M.A., M.D., B.Ch., D.P.H., as bacteriologist at their antitoxin establishment, Belmont Laboratories, Sutton, Surrey, of which Dr. R. G. White is the director. Dr. Todd has been research assistant in the inoculation department of St. Mary's Hospital since January, 1924.

FOR the forthcoming international competition for the detection of mustard gas in the air the assessors appointed by the International Red Cross Committee are: Professor F. Haber, Berlin; Sir William Pope, F.R.S., Cambridge; Professor F. Swarts, University of Ghent; and Professor G. Urbain, Paris; with Professor J. Demolis, University of Geneva, as secretary. The assessors, who will elect their own president, will meet in April, 1931, at the University of Paris, to examine the proposals submitted to them by competitors, and to award the prizes offered by the International Red Cross Committee for reagents for the detection of mustard gas in the air.

THE French League against Cancer announces that donors have placed at its disposal two prizes of 100,000 francs each for the encouragement of research on cancer. Further information can be obtained from La Ligue Contre le Cancer, 2 Avenue Marceau, Paris.

THE Eighth International Congress of Dermatology will be held at Copenhagen from August 5th to 9th, 1930, when the chief subjects for discussion will be the etiology of syphilis and eczema, immunity, reinfection, and superinfection.

THE second Italian Congress of Eugenics will be held in Rome from September 30th to October 2nd, with his Excellency Benito Mussolini as president of honour and Professor Corrado Gini as president. Further information can be obtained from the general secretary, Istituto di Statistica e Politica Economica, 10, Via delle Thermo di Diocleziano, Roma.

THE sixth annual report of the *Journal of the American Medical Association* on the mortality from diphtheria in the eighty-one large cities of the United States, with a population of more than 100,000, shows that every one of the eight geographical divisions had a lower diphtheria death rate in 1928 than in 1927.

IN 1928 only 2 cases of small-pox occurred in Germany, both of a mild type, as compared with 4 in 1927 with one death, and 7 in 1926 with no deaths. In England and Wales the number of cases of small-pox in 1928 was about 12,400.

AN institute of forensic medicine has recently been opened at the University of Frankfort.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the *British Medical Association* and the *British Medical Journal* are *MUSEUM 9561, 9562, 9563,* and *9564* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocrity Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, *Drumsheugh Gardens,* Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF LOCALIZED PULMONARY TUBERCULOSIS.

"W. J. D." asks for advice in the treatment of a man, aged 27½, who has pulmonary tuberculosis. The symptoms are slight; there are about eight expectorations per day, no night sweats, and no loss of weight. Fatigue and the existence of sputum are the chief trouble. Would the best treatment be to send him to Switzerland for a year? An *x*-ray examination revealed one small cavity in the apex of the right lung and two small ones in the left apex.

TREATMENT OF FUNCTIONAL TACHYCARDIA.

"PUZZLED" asks for suggestions as to diagnosis and treatment in the case of a man, aged 54, who has suffered from attacks of tachycardia at intervals during the last twenty years. They caused very little discomfort until recently, but are now occasionally accompanied by a feeling of anxiety or dread of impending death. They last two or three minutes; a few of the longer and more severe ones ended with vomiting and shivering. Though liable to attacks at any time, the patient has remarked that they often occur after eating or drinking; he has, however, often had one in the middle of the night. Pain is entirely absent. Soon after the attack the patient feels well, but he may have irregular heart action for a day or two following. There is a reduplicated cardiac first sound, but an electro-cardiogram (taken twice) has not been helpful. The teeth have been *x*-rayed and all stumps removed. There is a very dilated and dropped stomach, and the large intestine is similar; the patient wears an abdominal support. He is a non-smoker and moderate drinker. He has taken purgative medicine almost every night for many years. He is thin and not quite 10 st. in weight, but is able to play eighteen holes of golf without any undue fatigue. There is no albuminuria. If he could get rid of the very distressing feeling which accompanied his recent attacks, he says he would not worry about the tachycardia.

A POSSIBLE SECONDARY STREPTOCOCCAL INFECTION OF THE FEET.

"M. D." writes: I shall be glad to learn if any fellow members have met with circumstances similar to the following, and relating, unfortunately, to myself. A fortnight ago I suffered from a mild general inflammation of the tonsils and soft palate, together with painful enlargement of the cervical glands, some fever, and malaise, probably a streptococcal infection. A chlorine gargle was used and symptoms were subsiding, when suddenly, on July 18th, all the toes of my right foot, the small one excepted, together with the great toe of the left foot, became swollen, inflamed, and acutely painful. I am confined to bed, and, on July 20th, I feared incisions might be needed in some of the toes. The following day my temperature had fallen, the general pain, etc., were subsiding, and resolution was taking place. The toes affected were those employed in driving the car, which I had used a little more than was my custom during the week. I believe the symptoms to be due to a little excess of the use of my feet at a time when my blood was charged with a streptococcal infection. Hot weather, and a thin and too pliable sole, may also have played parts not unimportant.

TREATMENT OF A STRAINED LEG.

"V. S." writes: Six months ago I sprained my right foot. Leaving my seat in a dark cinema, I forgot the seats were raised and hooked myself up on the step at the side; the heel of the boot kept my foot suspended for some seconds. It was a forward "hook." The leg did not swell, but there has been persistent pain and tenderness at times, especially up the course of the peroneus tendon and tendo Achillis, and also in the region of both malleoli and in the heel. Doubtless there was some stretching and tearing of tendons and ligaments. I have had the foot strapped, also massage, some diathermy, and ionization. Faradization set up acute pain, but ionization helped. Can anyone suggest further treatment? I lose confidence when driving the car.

PAINFUL HEEL.

DR. PERCY HALL (London, W.1) writes: In reply to the question of "Ajax" on July 20th (p. 130), I may say that I have treated a number of patients—usually middle-aged men—with this condition. I regard it as a fibrositis, rheumatic or gouty in origin in most cases. Diathermy applied direct, with massage and manipulations, will in most cases effect a cure.

INTESTINAL STASIS WITH SPASM.

"B. M.," whose query under this heading appeared last week (p. 130), writes to say that the patient's age is 62, and not 42, as printed.

DR. G. C. CATHCART (London, W.) writes: I am much interested in the letter from "B. M." (Boscombe), who asks advice for treatment in a case of a patient with colitis and constipation, who is "always tired and seems to have severe toxæmia." In 1927 I published a paper on "Tonsillectomy in adult patients," in which I said that several cases of colitis, which had resisted all the usual methods of treatment, had been cured by tonsillectomy; since then I have had some others. All these cases had the symptoms of being "always tired," which disappeared shortly after the operation. I would suggest, therefore, that the condition may be kept up by septic tonsils. If so, it will probably be cured by their removal.

"J. F." (London) writes: Perhaps the advice of a dyspeptic who, in his 72nd year, still enjoys his work, as the result of careful dieting, may be worth noticing. Eliminate porridge, wholemeal bread, ham, cheese, puddings, pastry, jam, and acid fruits; these in my own case produce acidity, drowsiness, and headache. Allow plenty of well-cooked New Zealand lamb (English is tough and new), white bread, white fish, poultry; no new potatoes less in size than a hen's egg. Eat cabbage, young peas, French beans, and boiled celery, but no sprouts, cauliflower, spinach, or parsnips.

INCOME TAX.

Purchase of Share in Practice.

"R. L.," after being an assistant to Dr. S. for a few months, commenced, on January 1st, 1928, a two years' partnership introduction. The practice accounts are made up to March 31st of each year, and the assessment for the financial year 1928–29 was made on the basis of the practice accounts for 1927–28. The profits for the year 1928–29 have fallen short of the sum assessed by £350, but the inspector of taxes states that there is now no remedy, and that the assessment for that year must stand.

*** We presume that "R. L.'s" salary for the period to December 31st, 1927, has been treated as an expense in arriving at the profits of the practice for the year ended March 31st, 1928; if this has not been done the facts should be explained and an adjustment of the assessment for 1928–29 asked for accordingly. On the technical merits of the question the inspector of taxes is correct, though if it could be shown that the change in the constitution of the practice reduced the earnings for the period January 1st to March 31st, 1928, some adjustment might be obtainable. We gather, however, that the facts would not support this form of application.

Cash Basis.

"S. M. V." bought a practice a year ago, and has been informed by the inspector of taxes that for his first three years he must pay on an earnings basis.

*** This is correct. In the case of a new practice the cash receipts do not represent the full earnings of the practice. He should, however, take care to examine the list of debts outstanding at the end of each year, and to deduct reasonable amounts in respect of specific debts for which he considers he is unlikely to receive payment in full.

Motor Expenses: Salaried Appointment.

"A. P." and his wife were both whole-time medical officers of a local authority, he receiving a fixed allowance of £100 for motor expenses and his wife an allowance of 5d. per mile. The wife resigned her appointment and "A. P." sold his car and bought his wife's for professional use by himself. He has claimed obsolescence allowance accordingly, but the inspector of taxes refuses to admit it on the ground that the motor expenses—the whole of such expenses and not merely running costs—are borne by the local authority in the form of an expenses allowance, and cannot therefore be set against "A. P.'s" assessable salary.

*** It seems to us immaterial that the car was bought from the wife, and that the real point in dispute is whether the £100 is adequate—in the circumstances following the wife's resignation—to cover the expenses "incurred wholly, exclusively, and necessarily" in the performance of his duties. The practical difficulty, of course, is that any such inadequacy would normally be a matter for "A. P." to press on the local authority, and the acceptance without energetic protest of that amount is likely to prejudice his claim that for income tax purposes it should be regarded as insufficient. "A. P." might be well advised to approach the local authority first, pointing out that the allowance is not enough to cover depreciation as well as running costs. If he gets no direct satisfaction he may extract some statement as to the basis on which it is computed which will assist him in his negotiations with the income tax authorities.

Motor Cars: Private Use.

"J. M. B." has been using two cars, A and B, of which B has been used substantially for private purposes. Some time ago it was agreed that there should be excluded from the car expenses, to cover private use, £50 *plus* three-fifths of the depreciation applicable to B. That car has now been disposed of and a higher-powered second-hand car C bought in replacement. The obsolescence allowance claim for B is £97, of which the inspector proposes to allow £9 only—that is, two-fifths of £97. The result is to disallow for private use a total amount which is distinctly in excess of that applicable to the year in question.

*** The obsolescence allowance is in substance a postponed depreciation, and it is difficult to suggest any grounds on which our correspondent can base his claim to discard the three-fifths and two-fifths basis for the year in question. It is—as he says—particularly difficult to deal with, because the converse will arise when A is sold and replaced. Probably the basis adopted—namely, the isolation of one car as the one used privately—was bound to lead to trouble sooner or later. A definite amount estimated in round figures each year, and, having regard to the actual amount of private use in that year, is preferable. We advise "J. M. B." to have a personal interview with the inspector, pointing out to him the converse position that will arise when A is sold and asking him to agree to an amount—to include depreciation and obsolescence—to be added back to the net profit for private use.

Motor Car Allowance.

"X. X." is a consulting surgeon with rooms in the West End, but resident in the suburbs. His work necessitates visiting cases near his consulting rooms and daily attendance at hospitals in Central London to carry out his honorary duties. The inspector of taxes has refused the motor car allowance on the ground that that expense is not incurred in performing his work.

*** It must be admitted that the expense of travelling from the residence to the place where the work is performed is not strictly allowable by law—it is, for instance, analogous to the city worker's season ticket. But, in our opinion, the holding of honorary hospital appointments and the performance of the duties attached thereto are a natural and usual adjunct to a consulting surgeon's practice. To carry out such duties the use of a car is a recognized necessity, and we consider that such portion of the motor car expenses should be allowed as fairly represents the cost of travelling about visiting patients at the hospitals or elsewhere. Possibly "X. X." can persuade the authorities to make an allowance on the basis of the total cost less the estimated expense incurred in travelling from and to his residence and in other private use. As the car is required primarily for professional purposes, that would seem to be a reasonable basis.

LETTERS, NOTES, ETC.

THE "MEDICAL DIRECTORY."

WE are informed by the Editors of the *Medical Directory* that the annual circular has been posted to each member of the medical profession; if the form has not been received a duplicate will be sent on request. They hope for the return of the completed forms by an early post to them at 40, Gloucester Place, Portman Square, W.1.

CHRONIC ARTHRITIS.

DR. WM. J. MIDELTON (Bournemouth) writes: I have read with interest the articles and correspondence concerning arthritis which have appeared in the *British Medical Journal* recently. I agree with those who say we have too many labels in connexion with rheumatic ailments. Many years ago Dr. R. L. Jones-Llewellyn suggested chronic cerebro-spinal toxaemia as a substitute for the term rheumatoid arthritis, and it is a matter of regret to me that it never came into use. When dealing with a case of arthritis I try to forget that the patient has any joints; I think of the central nervous system and the endocrine system. To me these are of far greater importance than the joints. I believe that in all cases of chronic arthritis they are affected little or much. I am a whole-hearted believer in the germ theory, but I have difficulty in accepting the view that staphylococci, streptococci, the *B. coli*, etc., are ever the chief cause. I think that some infective malady, even one so apparently slight as measles or chicken-pox, may be a main factor in the production of arthritis. I hold that germs may linger in the system for an indefinite period. None of the writers have called attention to tuberculosis as a factor, in spite of the fact that French authorities have given great prominence to this. I find, personally, that non-specific treatment, skilfully handled, acts admirably in dealing with rheumatic ailments. Of course, if a pneumococcus or a *B. influenzae* (Pfeiffer) can be found, then an autogenous vaccine should be utilized. As many of your readers are aware, for nearly thirty years I have pinned my faith to continuous counter-irritation, and I have yet to find a method of treatment that I can handle more efficaciously.

TREATMENT OF VENEREAL DISEASE IN MANCHESTER AND SALFORD.

DR. E. TYTLER BURKE, venereal diseases medical officer to the city of Salford, writes: Might I point out a mistake in The Handbook of the Meeting of the B.M.A. in Manchester? On page 61 it is stated that St. Luke's Hospital "is the chief hospital for the treatment of venereal diseases in the district." It would appear from the following figures that this honour belongs to Salford Municipal Clinic.

Item.	St. Luke's Hospital, 1927.	Salford Municipal Clinic, April 1st, 1928, to March 31st, 1929.
New cases...	1,232	1,597
Intermediate treatment	19,784	35,144
Medical officers' attendances ...	14,200	14,135
Total attendances...	33,984	49,279

WATER WASTERS.

MR. THOMAS W. GOMM, honorary secretary, the Pure Rivers Society (1, Lincoln's Inn Fields, W.C.2), writes: During this period of drought, when everyone is being called on to use less water, it is desirable to point out that the greatest water wasters of all are the authorities and individuals *who pour into our* pure rivers crude sewage, trade wastes, and filth of every kind, and quite unlawfully render the natural water supply unfit for drinking, or agricultural and other trade purposes.

"PRACTIPEDISTRY."

A LONDON SURGEON sends us the following ingenuous letter, which he has received this week:

> Dear Sir,—On the advice of two Doctors that are in the Harley St. area, I am sending to all my address as that of an expert Chiropodist & practipedist. I trust that should you ever have the need to use the same, that you will do so with the full assurance that all that can be done for your patient will be done. Thanking you in anticipation, I beg to remain, Yours faithfully,—

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 36, 37, 40, 41, and 42 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 39.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 76.

de KUYPER'S

HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 233 years.

KROME-PLATE SURGICAL INSTRUMENTS

GIVE LONG LIFE AND RELIABLE SERVICE

DONIGER Krome-Plate Surgical Instruments have proved their definite superiority over ordinary nickel-plate. They are manufactured by highly specialised craftsmen from pore-free high carbon steel. After being polished until they are perfectly smooth and bright, then they are nickel-plated in the usual way, and finally given a heavy plating of chromium. This special process makes Doniger Instruments:

(a) much harder and stronger;
(b) rust-resisting;
(c) last five times as long as nickel;
(d) retain their original brightness.

Doniger Instruments have been tested over and over again in large hospitals and clinics in America and have always given complete satisfaction. In spite of their many advantages they cost very little more than ordinary nickel-plated instruments.

You are invited to apply to your usual Supply House for full particulars and prices.

Doniger Instruments are not supplied direct to the Profession.

CITY OF LONDON MENTAL HOSPITAL, DARTFORD, KENT.

PRIVATE PATIENTS are received at a weekly charge of TWO GUINEAS and upwards.

Voluntary BOARDERS can now be admitted.—Apply to the MED. SUPERINTENDENT.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS, NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56. Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

NEURASTHENIA
BELVOIR NURSING HOME, ASTON-ON-TRENT, DERBY.

Private Nursing Home for Neurasthenia and allied Functional Nervous Disorders, for general Convalescent Cases, and those requiring Electrical Treatment.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicin ment is used extensively in suitable cases. Certifiable cases are n atment, Radiant Heat, X-ray, Ultra-violet Light, and Massage is Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week ply to—
Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. Telephone: Shardlow 16.
Dr. Douglas-Morris can be seen by appointment in London.

UNIVERSITY OF BIRMINGHAM

FACULTY OF MEDICINE

(Associated with the General, Queen's, and Special Hospitals for Clinical Teaching.)

THE SESSION OPENS ON MONDAY, SEPTEMBER 30th, 1929.

The University grants Degrees in Medicine, Surgery, and Public Health, and a Diploma in Public Health; also Degrees and a Diploma in Dental Surgery.

The courses of instruction are also adapted to meet the requirements of other Universities and Licensing Bodies.

HOSPITAL APPOINTMENTS.

A large number of Resident Hospital appointments in Birmingham and District are open to qualified students of the School.

SCHOLARSHIPS, EXHIBITIONS, AND PRIZES.

Entrance and other Scholarships and Exhibitions and various Prizes and Medals are awarded annually in the Faculty of Medicine.

SCHOOL OF DENTISTRY. (University of Birmingham and Birmingham Dental Hospital.)

The School of Dentistry, in conjunction with the General and Queen's Hospitals, affords a complete curriculum for the Dental Diplomas and Dental Degrees of the University and all other Licensing Bodies. There is a Dental Scholarship of the value of £46 17s. 6d. offered annually.

PRE-MEDICAL AND PRE-DENTAL EXAMINATIONS.

The necessary Courses of Instruction in Chemistry and Physics and in Biology may be attended in the University.

RESIDENCE FOR UNDERGRADUATES AND OTHER STUDENTS.

There are Halls of Residence for Men and for Women Students. A register of approved lodgings is also kept by the Secretary of the University.

For Syllabus and further information apply to Prof. J. O. BRASH, M.A., M.D., Dean.

LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL.

THE WINTER SESSION will Open on Tuesday, October 1st.

The Hospital is the largest in England. There are 839 beds in constant use. Last year: number of in-patients 14,698; new out-patients, 95,928; attendances, 555,762; new dental patients, 5,857; major operations, 7,649.

The MEDICAL COLLEGE and DENTAL SCHOOL are essentially modern, with large laboratories equipped with the latest and the most approved appliances. The STAFF is so large as to permit of individual attention being paid to all Students.

MEDICAL UNIT.—A Clinical Unit in Medicine, under the charge of a whole-time Director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research.

RESEARCH FUNDS to the value of over £113,000 permit of financial assistance being given to Students and Graduates engaged in Medical Research.

SCHOLARSHIPS and PRIZES to the value of £1,158 are awarded annually, including four Open Entrance Scholarships to the value of £350, and two Entrance Scholarships open to students of the Universities of Oxford and Cambridge to the value of £200.

APPOINTMENTS.—Over 160 Appointments are made annually from Students of the College recently qualified.

SPECIAL COURSES are held for all the University Examinations, for the Primary and Final Fellowship Examinations of the Royal College of Surgeons, and for the Membership Examination of the Royal College of Physicians.

HOSPITAL PRACTICE.—Exceptional opportunities are offered to qualified Practitioners wishing to attend the General Practice or the Practice of a Special Department of the Hospital.

A Clubs' Union, an Athletic Ground of over 13 acres, and a *Students' Hostel*, promote the recreation, health, and comfort of the Students.

For Prospectus and Particulars apply to the Dean (Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S.), who will be pleased to make arrangements for anyone wishing to see the Medical College and Dental School.

MILE END, E.

—PATHOLOGIST required. Salary £400 to £500 per annum. Applications, stating qualifications, with testimonials and references, to be lodged with the Secretary, 156, St. Vincent Street, Glasgow, C.2.

Egyptian Government.

EGYPTIAN UNIVERSITY.

Applications are invited for the post of PROFESSOR OF CLINICAL PATHOLOGY.

The salary offered is £E.1,500 (about £1,550) a year without pension, and the appointment will be on contract for five years, but may be renewed by mutual consent for a further period.

The Professor of Clinical Pathology will be expected to organize the work of the Department of Clinical Pathology in its relation to the Kasr-el-Aini Hospital and to give such courses of instruction as may be decided upon. Preference will be given to candidates possessing a special knowledge of diseases of warm climates. The appointment is to be a full-time post, no private practice being allowed.

An allowance equal to one month's salary will be paid on arrival at Cairo for travelling expenses.

Applications, accompanied by testimonials and references, to be addressed to the Dean, Faculty of Medicine, Egyptian University, Cairo, so as to be received not later than September 15th, 1929.

County of Aberdeen.

PUBLIC HEALTH DEPARTMENT.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from qualified Medical Men and Women for the post of Assistant Medical Officer of Health (Junior) under the Joint Committee for Public Health Services for the County of Aberdeen.

Applicants must possess the Diploma in Public Health and have had previous experience in public health work, especially maternity and child welfare work. The duties will also include the examination of school children and general public health work within a definite area. The successful applicant will be required to reside in a centre within the County other than the City of Aberdeen.

The salary will be at the rate of £500 per annum, with increments of £25 per annum for ten years. Travelling and other expenses will be allowed according to the Committee's scale.

Applications (forms for which may be obtained from the undersigned) must be lodged with him, together with twelve copies of three recent testimonials, not later than August 17th next.

County Buildings, Aberdeen. July 20th, 1929. WILLIAM MURISON, County Clerk.

County Borough of Rochdale.

ASSISTANT MATERNITY AND CHILD WELFARE MEDICAL OFFICER (Lady).

The Health Committee invite applications for the appointment of Assistant Medical Officer for Maternity and Child Welfare.

Candidates must be fully qualified medical practitioners, with post-graduate experience in maternity and child welfare work, and in the treatment of venereal diseases in women.

The officer appointed will be required to devote the whole of her time to the duties of the appointment, which include attendance at the Ante-Natal, Maternity and Child Welfare, and Venereal Diseases Clinics, and the Infants and Children's Hospital. Also the inspection of, and lectures to, midwives, or any other public health duties assigned by the Medical Officer of Health, under whose directions and supervision such officer will act.

Salary at the rate of £600 per annum.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, Rochdale, and when completed should be returned, together with copies of three recent testimonials, so as to be delivered at this office not later than Thursday, August 8th. Envelopes must be endorsed "Medical Officer."

Town Hall, Rochdale. July 27th, 1929. WM. HENRY HICKSON, Town Hall.

City of Nottingham Education Committee.

Applications are invited from duly qualified and registered medical practitioners for the post of SENIOR ASSISTANT SCHOOL MEDICAL OFFICER.

The salary scale for the post will be £600 p.a., rising, upon approved service, by annual increments of £25 to £800 p.a. The Committee will, in fixing the commencing salary, take into consideration any special qualifications and experience of the selected candidate.

Applications, which should be made on the special forms obtainable from the undersigned, must be returned by August 30th.

Canvassing, either directly or indirectly, will be deemed a disqualification.

School Medical Service, 28, Chaucer St., Nottingham. A. H. WHIPPLE, Director of Education.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
Capt.			150	3rd
	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£50	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 21 years' total service	1500	£30	13th and over
	(ii) During 21th and 22th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are *not debarred* from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

			Per annum. £
After 17 years' service for pension			400
,, 18 ,, ,, ,, ...			430
,, 19 ,, ,, ,, ...			460
,, 20 ,, ,, ,, ...			500
,, 21 ,, ,, ,, ...			540
,, 22 ,, ,, ,, ...			580
,, 23 ,, ,, ,, ...			620
,, 24 ,, ,, ,, ...			660
,, 25 ,, ,, ,, ...			700
,, 26 ,, ,, ,, ...			750
,, 27 ,, ,, ,, ...			800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 *per annum* for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet in July to make nominations, and the selected candidates will be required to attend a course of instruction commencing on the 6th August, 1929.

County Borough of Croydon.

CROYDON MENTAL HOSPITAL, UPPER WARLINGHAM, SURREY.

APPOINTMENT OF SECOND ASSISTANT MEDICAL OFFICER.

The Visiting Committee of the Croydon Mental Hospital are prepared to receive applications from medical men for the appointment of Second Assistant Medical Officer at the Croydon Mental Hospital. No married quarters are provided.

The salary will be at the rate of £350 per annum, rising by annual increments of £25 each to a maximum of £450 per annum, and the age of the candidate should not exceed 35.

Furnished apartments will be provided, with board and washing, and for the purpose of Superannuation will be valued at £150 per annum.

Candidates must be registered under the Medical Act, and preference will be given to those candidates who have held the post of House Surgeon or House Physician at a General Hospital.

The appointment will be subject to the provisions of the Asylum Officers Superannuation Act, 1909.

Applications to be made on forms to be obtained by sending a stamped addressed foolscap envelope to the undersigned, with copies (not originals) of not more than three testimonials of recent date, not later than 11 o'clock in the forenoon of Thursday, August 8th, endorsed "Croydon Mental Hospital, Second Assistant Medical Officer."

Canvassing in any form is prohibited.

Town Hall, Croydon. JOHN M. NEWNHAM, Clerk to the Visiting Committee.

July 17th, 1929.

City and Port of Plymouth.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified medical men for the post of Assistant Medical Officer of Health to the City and Port of Plymouth.

Applicants should not be more than 35 years of age, and must possess a Diploma in Public Health, or a qualification in State Medicine, or a Diploma in Tropical Medicine.

The person appointed will be required to assist the Port Medical Officer from time to time as required, and he will also assist in the general public health work of the City and in the various sub-departments of the Public Health Department. He will be required to act under the general supervision of the Medical Officer of Health and to carry out any duties delegated to him from time to time.

The salary will be at the rate of £600 per annum, and the appointment will be terminable by three months' notice on either side.

Forms of application are not provided, and applicants should send a statement of their professional qualifications and experience, together with copies of not more than three recent testimonials, to the undersigned on or before Saturday, August 24th. Canvassing will disqualify the applicant.

Envelopes must be endorsed "Assistant Medical Officer of Health."

A. T. NANKIVELL, Medical Officer of Health, City and Port of Plymouth.

Town Hall, Stonehouse. July 15th, 1929.

City of Plymouth.

UDAL TORRE SANATORIUM, YELVERTON.

RESIDENT MEDICAL OFFICER.

Applications are invited from duly qualified and registered practitioners (male) for the post of Resident Medical Officer at Udal Torre Sanatorium (39 beds). The Sanatorium is situated on Dartmoor about 9 miles from Plymouth, and is reserved for the treatment of intermediate and advanced cases of pulmonary tuberculosis in male persons.

The salary will be at the rate of £450 per annum, together with board, residence, and laundry. Quarters are not provided for a married man. The appointment will be terminable by three months' notice on either side. Canvassing will be a disqualification.

The person appointed will rank as an Assistant Medical Officer of Health, and will be required to act under the general supervision of the Medical Officer of Health and to carry out any duties delegated to him from time to time.

Forms of application will not be provided, but candidates must state their age and experience.

Applications, together with copies of not more than three recent testimonials, must be delivered to the undersigned at his office on or before Saturday, August 24th, and envelopes must be endorsed "Resident Medical Officer."

Town Hall, Stonehouse. A. T. NANKIVELL, Medical Officer of Health.

July 15th, 1929.

Liverpool County Borough.

LOCAL EDUCATION AUTHORITY.

JUNIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited for a Junior Assistant School Medical Officer, in the Department of the Medical Officer to the Local Education Authority, at a salary of £600 per annum.

Applicants must be registered medical practitioners, and shall have had at least three years' experience. It is desirable that they should have had some special experience in school hygiene and in diseases of children.

The officer appointed will be required to devote his whole time to the service of the Education Authority, under the direction of the Medical Officer to the Education Authority. He will not be allowed to undertake private practice, and will be required to contribute to the Liverpool [illegible] Scheme, as required the City Council.

[illegible] qualifications, etc., [illegible] ot more than three endorsed "Junior Assistant School Medical Officer," must be delivered at the office of the Town Clerk, Municipal Buildings, Liverpool, on or before August 27th.

Canvassing of members of the Committee or the City Council is strictly prohibited, and will be considered a disqualification.

WALTER MOON, Town Clerk and Clerk to the Local Education Authority.

Municipal Buildings, Liverpool. July 20th, 1929.

Salisbury Municipality

MEDICAL OFFICER OF HEALTH.

Applications are invited for the position of Medical Officer of Health to the Salisbury Municipality, at a salary of £900 per annum.

Applicants must possess the Diploma of Public Health.

Duties will include those prescribed by the Local Government Board (England) for Medical Officers of Health and, in addition, the medical examination of natives in the Municipal Area; attendance on natives at the Lazaretto; and European patients at the Isolation Hospital.

The officer appointed will be the administrative head of the Sanitary and Public Health Department.

Applicants must state age, and whether single or married, submit qualifications and present occupation, together with three testimonials.

Applications close on August 31st, and must be addressed to the undersigned, endorsed "M.O.H." on the cover.

The successful applicant will be required to assume duties as soon as possible after October 15th. No travelling expenses will be paid, but salary will commence from date of leaving to take up duties.

By Order of the Council,
R. L. POLLETT, Town Clerk.

Town House, Salisbury, SALISBURY, S. RHODESIA.
June 25th, 1929.

West Derby Union.

RESIDENT ASSISTANT MEDICAL OFFICER (Male).

The Guardians invite applications for the appointment of a male Resident Assistant Medical Officer at the ALDER HEY CHILDREN'S HOSPITAL, WEST DERBY, LIVERPOOL (800 beds), at a salary after the rate of £200 per annum, together with the usual resident allowances.

Candidates must be single, fully qualified, and registered.

The appointment will be for a period of one year in the first instance, subject to extension for a further period not exceeding twelve months at the option of the Guardians.

Applications to be sent, stating age, qualifications, etc., with copies of three testimonials, to the undersigned, not later than Tuesday, August 6th.

G. O. HOLLOWAY, Clerk to the Guardians.

Union Offices, Brougham Terrace, Liverpool.

Miller General Hospital,

Greenwich Road, S.E.10.

CASUALTY OFFICER (male and unmarried) required. Salary £150 per annum, with board, residence, and laundry. The appointment is for the period from August 13th next until March 31st, 1930.

Applications, stating age, nationality, qualifications, and experience, accompanied by copies of not more than three recent testimonials, to be sent to the Secretary as soon as possible.

July 23rd, 1929.

County Borough of Rotherham,

DEPUTY MEDICAL OFFICER OF HEALTH, TUBERCULOSIS OFFICER, and RESIDENT MEDICAL OFFICER.

OAKWOOD HALL SANATORIUM.

Applications are invited for the above post at a salary of £650 per annum, together with a house and certain other emoluments valued at £25 yearly. Candidates must be duly qualified and registered, possess the D.P.H., or other similar qualification, and not be over 45 years of age. The Sanatorium accommodates 100 patients, and preference will be given to applicants with a knowledge of X-ray work. While the main duties of the office will be in connection with Tuberculosis, the officer will be required to undertake other work relating to the Infectious Diseases Hospital and General Public Health, and be prepared to act under the instructions and general superintendence of the Medical Officer of Health. The successful candidate will be required to devote the whole of his time to the duties of the office and, subject to a recent satisfactory medical certificate being provided, to contribute to the Rotherham Corporation Superannuation Fund. The appointment will be subject to the approval of the Ministry of Health. Three months' notice to be given to terminate the engagement. Applications, accompanied by three recent testimonials, must be sent to me, endorsed "Deputy M.O.H.," not later than August 7th next.

CHAS. L. DES FORGES, Town Clerk.

Municipal Offices.

SALTAIR SURGICAL SERVICE

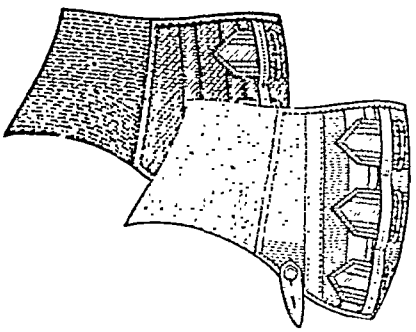
Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

Lighter clothing & lighter food for warm days

WHY NOT LIGHTER APPLIANCES?



The alternative wearing of two appliances—one for winter and one for summer—ensures hygiene economy and bodily comfort.

In the summer the winter appliance can be sent to us for repair, cleaning, and rehabilitation.

Medical Men are urged to point out to their patients the comfort and economy of such a method.

'CHARKAOLIN'
GRANULES

A Combination of Highly Activated Charcoal with 'Osmo' Kaolin

'Charkaolin' is a new and highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of 'Osmo' Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. 'Charkaolin' is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

The Therapeutic value of BRANDY—

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them.

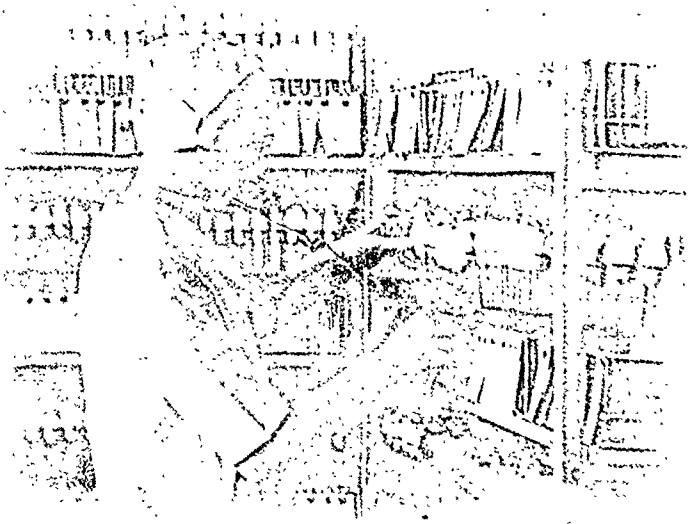
Take no risks; ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe MARTELL'S BRANDY

and know that you are doing the best possible for your patients.

VERIFIED STERILITY



Rigid bacteriologic tests for the presence of both aerobic and anaerobic organisms are conducted on each lot of

D & G Sutures

Greater Comfort for Your Patients.

"The Rose Corset-Belt"

which has set a new standard and proved so effectual in all abdominal cases where support is required. The X-rays have shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

DOCTORS

prescribe "ARDENTE"

because they know it is fitted from a wide range of distinct types—very inconspicuous—devoid of extraneous buzz—true-to-tone for conversation, music, church, theatre, public and school work. They also know that the guaranteed "Ardente" carries a genuine "after-sale-service"

Every important Medical Journal in the land has commended Mr. R. H. DENT'S world-famous aid for its efficiency and simplicity, and, if greater proof were required, it lies in the fact that

for their *DEAF* patients.

many DEAF DOCTORS use "ARDENTE"

"ARDENTE" STETHOSCOPE.—Mr. R. H. Dent also makes a stethoscope specially for members of the medical profession suffering from deafness, slight or acute. Many are in use, and excellent results are reported.

MEDICAL REPORTS SENT ON REQUEST.

309 OXFORD STREET, LONDON, W.1

Free Home Tests Arranged

for Doctors and their patients or at the addresses below.

Medical prescriptions carefully made up.

SURGICAL SERVICE
SALTAIR

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

Suit the Appliance to the Season.

OCTOBER
NOVEMBER
DECEMBER
JANUARY
FEBRUARY
MARCH

Practically everybody discards heavy underclothing for lighter weight during the summer months, yet patients doing this frequently retain their Winter appliance, being unaware of belts of more porous texture.

The ordinary belt when worn during the Summer induces excessive perspiration, thereby shortening the life of the appliance.

Warmer days call for lighter clothes—why not for more suitable appliances also?

Patients will welcome eagerly the added comfort and complete freedom of movement for outdoor exercises afforded by

PEACE

Evening. A faint rustle in the trees. A few notes, melodious and low, from a night songster. In the garden world and worry is forgotten. In lazy comfort, sheltered from winds, one may talk a little, smoke a little, or drift into a blessed silence. Only nature will be busy; dosing the body gently with pure fresh air.

John Ward, Specialist in Invalid Chairs, respectfully invites members of the Medical Profession to write for the "Wardway Booklet No. 9."

JOHN WARD Ltd
242-7 Tottenham Ct. Rd. London

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the tonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

Novopine Sparkling Pine Bath Tablets

for nervous & heart disorders, rheumatic conditions, etc., etc.

Prepared & Prescribed for the treatment of:

Sphagnol products include SOAPS— LOTIONS— OINTMENTS— SUPPOSITORIES. &c. &c.

all skin affections such as ACNE, ALOPECIA, ANAL FISSURE, BLEPHARITIS, ECZEMA, ERYSIPELAS, PSORIASIS, SCABIES, etc.

Thousands of doctors have testified to the remarkable antiseptic and curative properties of the Peat Distillate principles in Sphagnol.

One writes:—"*I have frequently prescribed your preparations during the past five years and have not had a failure so far. For SEBORRHŒA of the scalp I invariably prescribe your soap.*"

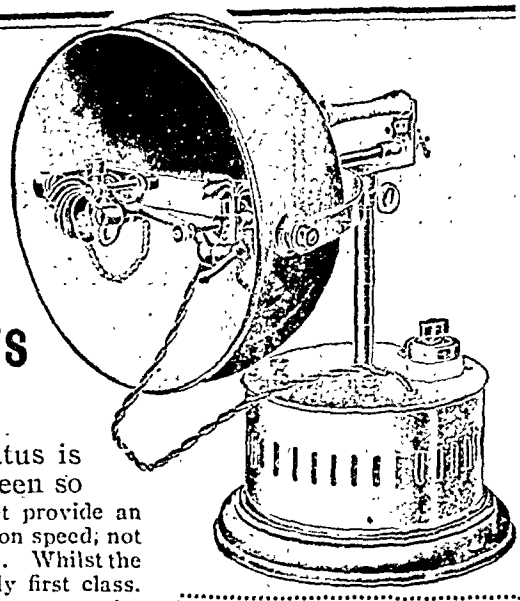
"MEDISUN"

ULTRA-VIOLET LIGHT APPARATUS

100% BRITISH.



Specification:

The "MEDISUN" Ultra-Violet Light Apparatus is of the quartz mercury vapour type. It has been so designed as to eliminate all unnecessary expense, and yet provide an efficient source of ultra-violet radiation, quick in its reaction speed, not requiring adjustment, and foolproof in its mechanical details. Whilst the price of the "Medisun" is quite low, its appearance is really first class. Manufactured in polished aluminium throughout, it does not require frequent cleaning, is designed to stand on any table, weighs only 14 lb., and is a thoroughly reliable piece of apparatus.

RUNNING COST: **30 TREATMENTS 3d.**

Price:

For use on Direct Current ... £12
For use on Alternating Current £18

THIRTY OTHER TYPES

ANTISEPTIC CREAM
(Hewlett's).

An emollient healing cream for BLEPHARITIS, ACNE, ECZEMA, and all abrasions and irritation of the Skin.

Its soothing and healing properties are most marked.

In enamelled collapsible tubes, 18s. doz., or 1-oz. pots, labelled only "The ointment to be used as directed," 10s. 6d. doz.

In bulk, 5-oz., 10-oz., 22-oz., 40-oz., 4½ lb. & 7½ lb. pots, 5s. 6d. lb.

Introduced and Prepared only by
C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte Street, London, E.C.2.

Intestinal Disinfection

ALIMENTARY TOXÆMIA AND ENDOCRINE INSUFFICIENCY

A WRITER in THE LANCET has directed attention to an apparent connection between alimentary toxæmia and endocrine insufficiency, particularly of the thyroid gland. Many cases of "ill-health," neurasthenia and others, were benefited by the administration of thyroid extract.

He goes on to remark that there seems to be a close connection between endocrine insufficiency and poisoning from intestinal absorption, and notes the beneficial results obtained by the use of intestinal antiseptics in addition in these cases.

He seems to be unaware that the best of all intestinal antiseptics is Kerol. In endocrine insufficiency, therefore, use Kerol in addition to other measures.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Alimentary Toxæmia

Laboratory *v.* Clinical Results

The swing of the pendulum has recently caused certain bacteriologists to question the importance of alimentary toxæmia in the causation of a wide variety of diseases, on the ground that their fæcal bacterial counts are so untrustworthy that no standard of pathogenesis can be identified with any particular type of flora.

This, as most Medical Practitioners are aware, by no means represents the opinion of the great majority of Laboratory Experts, in whose hands the matter may be left for final settlement.

Meanwhile, the experienced Clinician will be guided by the results he obtains when ordering an approved non-toxic bactericide in the treatment of putrefactive and other bacterial invasions of the intestinal tract; and the more potent and less toxic the bactericide, the more assistance he will have in his other measures of treatment.

Medical Men who have continued to rely on Dimol in the treatment of intestinal disabilities of bacterial origin since it was first introduced to the Profession in 1921 will be interested to learn that after long and thorough investigation

DIMOL PULVERETTES ARE NOW SUPPLIED BY THE ADMIRALTY FOR USE IN HIS MAJESTY'S SHIPS AND ROYAL NAVAL HOSPITALS.

The Source of NOURISHMENT

VITAMIN B

Outstanding advantages of HOVIS

Of all kinds of bread consumed to-day, HOVIS is richest in Vitamin B, which encourages growth and increase of weight. Bulk for bulk it supplies a greater amount of nourishment.

HOVIS combines all the benefits of white flour with 25 per cent. of the wheat germ, the part richest in the vitamin, added.

Compared with other cereals, the Vitamin B content of milling products and yeast in 100 g. dried bread is as follows:

White Bread ...	200
Wholemeal Bread ...	1,450
HOVIS Bread ...	2,600

The great value of HOVIS is that it contains all the elements of a complete food; it is universally liked, and containing no bran is easily absorbed.

It is also most economical, the quantity necessary to furnish sufficient nourishment being very small.

Were HOVIS to form a part of everybody's daily diet the nation would undoubtedly be better nourished.

FOOD POISONING—
THE KAYLENE TREATMENT

The following letter has been received recently.

Messrs. KAYLENE, LTD. April 17th, 1929.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

VACCINE TREATMENT OF GONORRHOEA

In the treatment of Gonorrhoea the use of Vaccines, in conjunction with the usual routine treatment, materially shortens the course of the disease and prevents complications.

DETOXICATED VACCINES are recommended for preference owing to the massive doses which may be administered with little or no reaction, at the same time achieving great immunity, but where price is a consideration "Ordinary" Vaccines are available at very low prices.

For all early cases of Gonorrhoea, also in cases of Gonococcal Arthritis, Orchitis, Iritis, etc., Gonococcal Vaccine "A" is indicated. This is a pure Gonococcal Vaccine prepared from many strains (Polyvalent).

In cases of more than three or four weeks duration Gonococcal Vaccine "B" is recommended. This Vaccine is composed of equal parts of the above Vaccine "A" and the organisms found as secondary invaders in chronic cases.

Practitioners desiring additional information regarding the above Vaccines and also the special Gonococcal Products for Diagnosis and Test of Cure are invited to write to:

FIGURE ILLUSTRATIVE OF A HIGH STATE OF CIVILISATION EXISTING AT THE TIME OF THE FIRST INDIAN EMPIRE.

In estimating the part played by the ancient Indian pioneers and empire-builders in furthering civilisation, it has to be noted that their chief endeavour appears to have been directed towards conduct. They evolved, taught and aimed at practising an ethical religion which they desired should benefit all humanity. They sent out missionaries east and west, and their religion became that of all Asia, whose great monuments embody the inspiration they spread abroad. They instituted a form of government based upon the autonomous village community as a unit, which later rulers have found impossible to improve upon in a land composed of varied races and tongues. An ideal of peace and tolerance lay at its roots. "An Indian" writes a Greek historian at the court of the Emperor Chandragupta, "has never been convicted of lying." He further records that among 400,000 men in the emperor's camp there were no convictions for serious theft. The beautiful figure here reproduced bears silent witness to a lofty ideal of life and a high state of civilization which must have taken long ages in the making. After the decline of the Maurya dynasty the empire tended towards dismemberment into states having no cohesion. Later, a diminished empire appears to have come into being, but no enlightened ruler like Asoka arose for ten centuries—till the great Akbar came and restored India to a high place among the nations.

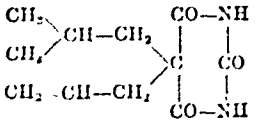
SANDOPTAL

A NEW HYPNOTIC



ISOBUTYL-ALLYL-MALONYLUREA

Clinical and laboratory tests have shown that Sandoptal fulfils to a high degree the conditions required in a hypnotic agent.

Sandoptal owes its advantages to a particularly favourable therapeutic index which permits sufficient dosage without harmful after-effects.

Sandoptal is sure and constant in action, and well tolerated by the aged.

It produces tranquil sleep of natural intensity and normal duration, and the awakening is net and accompanied by a feeling of freshness and general well-being.

It has been shown that Sandoptal is rapidly eliminated from the organism and that it does not produce exanthema.

DOSAGE:

Usual dose: 1 tablet, half to one hour before bed-time.

In obstinate cases: 1 to 3 tablets may be given (maximum dose 4 tablets).

TUBES OF 10 AND BOTTLES OF 100 TABLETS.

Observations
ON
X RAYS IN THE DIAGNOSIS OF EARLY CARCINOMA OF THE STOMACH.*

BY
PROFESSOR MARTIN HAUDEK, M.D.,
WILHELMINENSPITAL, VIENNA.

THE vital statistics of most countries show a steady decline in the birth rate and a contemporary increase in the average duration of life—in Germany an increase from the age of 38 to 57 years in the last decades. The decrease in the death rate is attributable to the progress of medicine, and especially to the methods adopted in grappling with the problems of infantile mortality, tuberculosis, and infectious diseases. One other fact stands out clearly from the statistics (in which in latter times diseases due to old age and debility greatly preponderate as causes of death)—namely, that *next to cardio-vascular disease comes cancer.* The war on cancer is therefore becoming a problem of ever-increasing importance to the medical profession.

Of all fatal cases of cancer, cancer of the stomach is shown to be the commonest. Its victims constitute a percentage of the total cancer deaths which varies in different countries from 35 to 40. Deaths from cancer of the intestine, uterus, œsophagus, and breast are far less common. So that if we are to wage effective war on cancer, then early recognition and treatment of cancer of the stomach are clearly indicated as the most promising line of attack. This is the reasoning which has apparently been followed by the Section of Radiology and Radiotherapeutics of the British Medical Association in selecting the early diagnosis of cancer of the stomach, and the relation of *x*-ray examination to that problem, as the subject for discussion at its first session.

SUCCESS ATTAINED UP TO THE PRESENT TIME IN RADIOLOGICAL DIAGNOSIS OF GASTRIC CANCER.

We can best envisage the prospects of success in the future by drawing upon the accumulated experience of the past; *x* rays have now been employed in the clinical diagnosis of gastric carcinoma for twenty years. During that time *x*-ray examination has in all countries become so general a practice in diseases attended by gastric symptoms that its omission amounts to a professional error. In many thousands of cases gastric carcinoma has been correctly diagnosed by its aid, and a very large number of patients have been submitted to radical operation. The number of *late* laparotomies—that is, operations at which incurable cancer was found—has decreased, as has also the number of *unnecessary* laparotomies, made as a result of a wrong diagnosis of cancer. *Exploratory* laparotomies, undertaken to clear up the doubt as to the presence of cancer, have become very rare, but were still of daily occurrence twenty years ago.

And again, on the question whether a gastric carcinoma is operable or not the *x* rays can give important information. This fulfils the expectation which I entertained as to the role of *x* rays in my paper, "Die Bedeutung der Magenradiologie für die Chirurgie," published in conjunction with Clairmont in 1911.[1]

As numerical evidence of the reduction of late laparotomies I quote the publication by Schönbauer and Freidel[2] of the Eiselsberg Clinic in Vienna "Ueber einige besonders lange Dauerheilungen nach Magenresektion wegen auch histologisch nachgewiesenen Carcinoma ventriculi." Of the 651 cases of *gastric carcinoma* in the period 1901–14, resection was done in 26.2 per cent.; of the 535 cases in the second period resection was done in 37.9 per cent. The primary mortality (18.5 per cent.) was the same in both periods. A comparison between the years 1908 and 1924 shows an increase of resections of 18 per cent. (from 22 per cent. to 40 per cent.). The increase in radical operations can be put to the credit of *x*-ray diagnosis, without, however, losing sight of the improvements in surgical technique. Yet 40 per cent. of possible radical operations still means more than 60 per cent. of operations undertaken too late—a figure which corresponds to the average of surgical statistics.

In the surgical department of the Wilhelminenspital in Vienna, for which I have done the *x*-ray examinations during the past nine years, the statistics show the same proportions. In all places must be added to these a great number of patients, in whom inoperability of the disease is recognized beforehand, so that not even an exploratory laparotomy is attempted. Thus the death rate in gastric cancer is still extraordinarily high.

How, then, can we attain to further progress? Are we merely to subscribe to the views of Boas (Berlin), the famous expert on gastric disease, who doubts the possibility of an early diagnosis of gastric cancer, on account of the more or less extended latent period connected with the disease? Those who have devoted much time to *x*-ray examination of the stomach, and have become convinced that *x*-ray methods allow gastric cancer to be recognized considerably earlier than by any other method of examination, will not incline towards pessimism, but will believe in the possibility of yet further progress.

CAUSES OF DELAYED RADIOLOGICAL DIAGNOSIS OF GASTRIC CARCINOMA.

We can distinguish four causes of delayed radiological diagnosis: (1) the latent period; (2) delayed *x*-ray examination; (3) faulty *x*-ray examination; and (4) a defect which still exists—namely, the incompleteness of our present-day technique.

The latent period—that is, the time during which gastric carcinoma remains symptom-free—is still the prime factor to be reckoned with. This period is of varying duration, depending on the type and site of the tumour. In carcinoma of the body of the stomach, especially with diffusely infiltrating growths, local symptoms often occur so late that, however prompt the examination, there is but rarely a chance of finding radical operation possible. The symptoms which lead to the earliest recognition of the growth are pyloric stenosis and haemorrhage.

Delayed x-ray examination has its cause, apart from latency, first in the often insidious origin of the disease and its indefinite symptoms; secondly, in non-recognition of the gravity of the local symptoms by the patient and his doctor alike. In the history of the cancer patient we usually hear of symptoms which have already existed, treated or untreated, for a considerable number of months, but at the same time we find such an advanced stage of carcinoma that we would have been quite able to diagnose the condition many months earlier. One way to improve the early diagnosis of cancer of the stomach would lie in eliminating this loss of many months' time and carrying out *x*-ray examination without delay.

Faulty x-ray examination is for us the most important subject. In my work, principally as consulting specialist, I have had many opportunities of convincing myself that the possibilities which an *x*-ray examination offers of deciding whether gastric cancer is present or no are not sufficiently utilized. I strongly maintain that by a sufficiently precise examination, supported by sufficient experience, we are in a position to establish at an early stage with a considerable degree of certainty whether a carcinoma is present or whether this can be definitely excluded. Since, however, the results of *x*-ray examination are often unsatisfactory, and since, in consequence, *x*-ray examination of the stomach does not enjoy the universal confidence which should be reposed in it, I must refer to the sources of errors.

At one time the difficulty of examination of the stomach was underestimated. Especially in connexion with *x*-ray examinations, the lay public, and unfortunately a good many doctors as well, think that the *x*-ray apparatus is the important thing for establishing a correct diagnosis. A man sometimes undertakes the work, without supervision, after a short period of mainly technical training, without possessing the rudiments of knowledge necessary for the responsible task of the radiologist. We must make everybody realize that *the result of an x-ray examination*

* A paper read in opening a discussion in the Section of Radiology and Radio-therapeutics at the Annual Meeting of the British Medical Association, Manchester, 1929.

depends far more on the skill of the investigator than on the quality of the apparatus.

The examiner, when he is an *x*-ray specialist, must arm himself with a thorough basic knowledge of pathological anatomy and internal medicine; similarly, a physician or surgeon who uses *x*-ray examination of the stomach independently in his cases must be familiar with general radiology. In cases where he does not feel certain of his own findings he must never hesitate to consult a radiologist with special experience. I find that *x*-ray consultation is far too seldom asked for, and this is a serious misfortune for the patient.

To attempt *x*-ray diagnosis of conditions of the stomach and duodenum without being able to employ photography as well implies a defective method. Although screen examination gives so much information, yet it must be supplemented by photography, and, moreover, by films taken with special skill and first-rate technique in order to obtain a permanent record of the significant signs. The diagnosis of early carcinoma, bound up as it is with the study of the "relief-pattern" of the mucous membrane, is, apart from radiograms, unthinkable. But even an experienced radiologist will surely make mistakes if too many examinations are required of him and if he undertakes them.

Personally I allow about half an hour for each examination I make, and will not undertake to carry out more than six to eight consecutive examinations. At the same time, I do not always complete a stomach investigation in one day, but sometimes explain that a second examination is necessary on the next day under different conditions. How, then, can those who carry out twenty or even thirty stomach examinations in a few hours expect to obtain equally good results? Such conditions do exist in many hospitals, and still more in the "panel" clinics, which are increasing in number. Superficiality and the danger of fatigue are inimical to accurate work. Many important or often in the interests of economy, which such conditions aids to diagnosis are perforce omitted for want of time, demand. Even if the results are only 10 per cent. worse than when the radiologist devotes himself entirely to his task of attaining a conclusive diagnosis, what patient would like to find himself among the 10 per cent. in which a stomach carcinoma is not recognized in time, simply because of insufficient examination?

Overburdening of the radiologist must therefore be stigmatized as a further source of error in the diagnosis of stomach carcinoma.

Technique and Method of Investigation of the Stomach.

There is no standard method or technique amongst radiologists engaged in stomach examinations. Neither screening nor radiography is carried out to the same extent or on exactly similar lines by different workers. But the whole outcome depends on bringing to light and critically analysing the appearances in detail.

I should like to describe my own method of investigation —a method progressively developed over twenty years. In every case I personally take an *accurate history of the illness*, because it forms a frame into which the *x*-ray findings are fitted; it is, however, often treated in a biased manner by the referring physician.

Screening of the chest is carried out before each abdominal examination. Often this reveals the cause of the symptoms hitherto ascribed to a carcinoma of the stomach; such as a serious aortic disease, or a tuberculous process in the lungs which may be accompanied by tuberculosis of the small intestine. We shall not be likely to overlook such lesions as metastatic carcinoma in the lungs, secondary malignant pleurisy, or a clinically undiagnosed bronchial carcinoma.

For screening of the stomach the patient stands on a low footstool, and I begin by *palpation* to estimate the tension of both *recti*, the possible presence of localized tenderness, or abnormal resistance. In weak and anaemic patients, and especially in those who are cachectic, I omit the palpation, otherwise the investigation in the erect position may be interrupted by the development of cerebral anaemia. The examination of the stomach usually begins with the *motility test*, four hours after the patient has taken a small portion of thick gruel with 70 grams of barium sulphate—so far just like the old Rieder meal. For the diagnosis of carcinoma this test for residue, apart from any secondary pyloric stenosis, may be of importance, inasmuch as a residue, or "surface film," on an ulcerated carcinoma may be the only visible remainder of the contrast meal.

Now follows the *second filling of the stomach*: this time not with gruel, but with a thick barium mixture just fluid enough to drink (double meal method). The total of this amounts to 300 c.cm., in which the quantity of barium is about 120 grams. Raspberry juice is employed to improve the taste. With the barium which I use (supplied by Merck) a special suspending agent is not necessary. The large quantity of barium used considerably diminishes the tendency of the contrast substance to sediment. Careful churning up with a whisk is sufficient to produce a suspension of the barium which will remain for a long time without sedimenting.

First of all the patient drinks only one large mouthful of about 20 to 30 c.cm. This is followed during its passage down the oesophagus. If the swallowing of fluid appears to me to be delayed in the least, or if the patient complains of difficulty in swallowing, I never omit giving him a small gelatin capsule filled with 1 gram of barium to swallow. If this, when followed by a drink of water, passes down the oesophagus and without hindrance through the cardia into the stomach, then a malignant stenosis can be excluded. Conversely, the holding up of the capsule, despite repeated drinks of water, is of great service in the early diagnosis of carcinoma at the cardia, whether originating in the cardia itself or in the upper part of the stomach. As an example I will quote the following case.

Case I.

Recently I examined a female patient of 60, whose symptoms appeared to the physician referring the case to be suspicious of stomach carcinoma. I found nothing unusual in the stomach except a slight diminution in size of the gastric air bubble on its medial aspect. Fluid barium flowed without obstruction into the stomach, and the gastric peristalsis and contour were quite normal. A small capsule, however, remained stationary close to the cardia. The film (Fig. 1) showed that the deformity of the

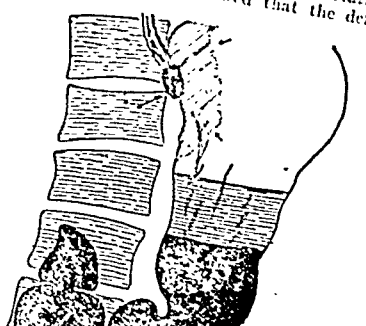

Fig. 1.—Medullary tumour in fornix. A small opaque capsule held up at the cardia. Stomach shadow elsewhere normal.

gas bubble was due to the shadow of soft-part density caused by a medullary tumour, which projected into the lumen of the stomach from the lesser curvature. The patient had no definite dysphagia, but only complained of the stomach. With screen examination alone, without the use of the capsule, I might have failed to observe it.

If the small portion of about 30 c.cm. of suspension passes into the stomach, it is dispersed by compression with Holzknecht's "distinctor" or a pad. The thin film of barium between the folds of the gastric mucosa throws them into clear relief. The "Magenblase" and the wall contours of the fornix, the course of the mucosal folds in the body of the stomach and in the pyloric segment are

examined successively with a small diaphragm and compression. *Retained secretion* interferes with the study of the mucosal "relief pattern." Secretion is recognized by a horizontal fluid level which is visible in the fasting condition below the Magenblase, by the paleness of the marking of the folds, by the very pale grey shadow which the contrast substance produces, and by an early crescentic sediment of the barium in the lower pole. If the marking of the folds is distinct, minute niches between the folds, or an abnormal thickness or irregular course of the folds, may be noticed. Irregular central shadow defects, or barium rests in the crater of a tumour or in the furrows between the lobules of a medullary carcinoma, lead to a definite diagnosis of tumour. With polypi or non-malignant tumours the borders are circular and well defined. After another drink the pars pylorica, the pylorus, and the bulbus duodeni become visible.

Now the patient drinks the remaining suspension, during which time the increasing filling of the stomach is watched, screening it at different angles. Observation is then directed to the flexibility of the walls, the sharpness and the regularity of the contours, and the course of peristalsis. With atonic stomachs the highest parts remain empty in the standing position. In these cases the contents of the upper third are dammed back while the patient drinks, by closing the lumen by pressure of the hand, or of the "distinctor" below the left costal margin. This procedure completely separates the folds in this part, which are now examined in different directions. In this way the very inaccessible tumours of this portion, so easy to overlook altogether, can be brought to light.

The usual examination in the standing position is often insufficient for the lesser curvature of the pars pylorica, the most important part of the stomach in the diagnosis of carcinoma. With atony, hypersecretion, and dilatation of the stomach, the contrast shadow is crescentic, and in spite of massaging the contents upwards, the lesser curvature is not reached by the barium and the bulb is poorly filled. In this case the patient is laid for a few minutes on a couch, on his right side, with the pelvis raised. After this preparation he is examined again standing up, and now the filling of the pyloric canal and of the duodenal cap is often satisfactory, or easily effected by pressing out the contents of the stomach. If manual manœuvres are impossible owing to the patient's condition—for instance, in anaemia, or with an inflamed irritated condition of the peritoneum, which may be recognized by increased tension of the rectus on one side—an examination with the patient lying down is most effective.

I attach great importance to the examination made in the *prone position*. In this position the contents of the stomach return from the backwardly directed fornix (formerly called "fundus" by the anatomists) into the ventral part—that is, the pars pylorica, which now becomes expanded to its maximum. The flexibility of the walls, the perfect curve of the pyloric terminal contour, and the normal convexity of the outlines are now most clearly visualized. *The prone position is indispensable for the examination of the peristalsis on the lesser curvature.* It must not be forgotten that quite a number of carcinomata are confined to the lesser curvature and leave the greater curvature completely free. In these circumstances perfect peristalsis is seen on the greater curvature in the standing position, and there is a risk of an early or even quite extensive disease of the lesser curvature being overlooked if it takes the form of a flat infiltrating growth.

The observation of the mucous membrane with partial filling, together with the flexibility of the walls and the regular course of peristalsis in the prone position, is the safest protection against overlooking a carcinoma. The diagnosis of small tumours depends on a scrupulous observation of this rule.

The object of Fränkel's (Berlin) cinematography is to diagnose rigidity of the walls in a small or large section of the lesser curvature by local absence of peristalsis. This is done by means of numerous photographs, taken in quick succession and projected on to a diaphragm. The photographs for this purpose are made in the standing position. The method of examination which I employ, and which I have just described, does, I think, render this expensive apparatus superfluous. As a matter of fact I decidedly prefer an examination of the peristalsis of the lesser curvature in the prone position to one made in the standing position; for the waves of both curvatures are of equal depth in the prone position because the pressure of the gastric contents then affects both curvatures in an equal degree.

I use the examination in the supine position in order to see the mucous folds in the pars pylorica, for in this position most of the contents of the stomach flow to the fornix, and the pars pylorica is then only scantily filled. But the examination in this position is of small importance compared with that in the standing and prone positions, and is employed only in rare cases.

A single *x*-ray examination gives the desired results in the great majority of cases, but not always. If the motility examination has shown gastric retention of food or secretion, then the detailed examination becomes more difficult, and its results cannot be relied upon as regards fine anatomical points. The patient has to come for a second examination, which may quite well take place on the following day. The patient takes only liquid in the evening and comes the next day for examination in a fasting condition. Before the examination he is made to lie on his right side for at least two hours, his pelvis being raised by a pillow. In this position the pylorus becomes the lowest point of the stomach, and the stagnant contents can be most readily removed. This method of evacuation of the stomach has served me better than evacuation by tube, which is usually incomplete. Into the completely emptied stomach is now introduced about 50 c.cm. of very thick barium cream, and the examination of the mucous membrane with compression is made in the standing and lying positions. Then the examination already described is continued with the full drink. If the preparatory measures just described have failed to remove the retained secretion, then there is either a pyloric stenosis, the cause of which, ulcer or carcinoma, can be ascertained, or there is hypersecretion of higher grade, due to ulcer. The diagnosis is made from the combination of the anatomical abnormality with disorder of function.

Photography is used at every important stage of the screening in order to fix the characteristic appearances. It is upon the care and judgement applied to the preparation of the part for the radiogram—whether by suitable filling of the suspicious segment of the stomach, by compression, or by the use of the correct diaphragm and the angle of radiation—that the whole prospect depends of obtaining pictures of decisive diagnostic value.

To distribute the contrast-substance to best advantage in stomach and duodenum I use Holzknecht's "distinctor" during screening, and when necessary, for quite short periods, one or even both hands. Though I have not used lead-rubber gloves, and have made innumerable examinations, my hands have in twenty years suffered no ill effects. The patient's body, with a tissue thickness of some 20 centimetres, constitutes in the usual antero-posterior examination an excellent protective medium. But, of course, exposure of the hands in the rays must be rigidly limited to the most important manœuvres of palpation or distribution of the contrasting substance. In making radiograms I use translucent pads (wadding sewn up in material) of various sizes to compress and spread out the barium.

The work of Berg[4] and Chaoul[5] has done much to popularize a similar technique. Berg prefers a very small diaphragm. Chaoul makes films giving a more extended view. He examines in the prone position on his special support, with a mirror below for observation, and makes compression with rubber air bags blown up to different degrees of tension. He uses a barium tragacanth mixture. I am engaged in trying out the suggested modifications of technique, but have not yet reached a definite decision whether, or to what extent, my own results can be thereby improved.

My own Results in Cancer Diagnosis.

Coming now to the results of my own examinations, I should like to test the reliability of my technique on three counts: Has it sufficed to determine slight changes

in the gastric wall? Have I overlooked an existing carcinoma? Or, on the other hand, has a commencing carcinoma been wrongly assumed to be present?

The number of really small carcinomata discovered by me in the earliest stage is very small. Much larger is the number of quite operable carcinomata which I have sent to operation. Most numerous of all my cancer cases have been those in which I was compelled to report inoperability.

Figs. 2 and 3 show a quite resectable tumour above the angulus. In the first, with a small meal, the mucous folds are shown, and terminate at the edge of a *dish-shaped* carcinoma. The second radiogram, after complete filling, shows what might be readily confused with an ulcer niche, because this also shows projection of the surrounding stomach wall into the lumen, due to swollen mucosa. But the folds *converge* towards an ulcer niche; they merely *terminate abruptly* before they reach a carcinomatous crater—a differential diagnostic point of great significance.

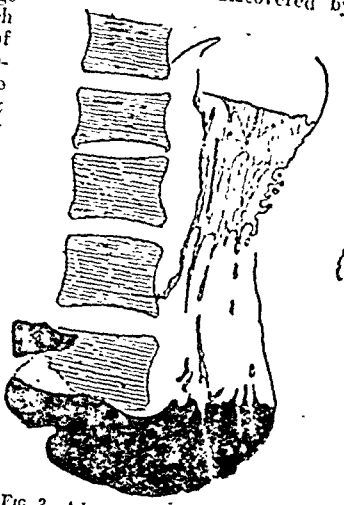

Fig. 2.—Adenocarcinoma at angulus. Mucosal "relief pattern" shows sudden interruption of rugae (arrow).

Fig. 3.—The same case with stomach completely filled. Carcinoma crater with infiltration and marginal ledges.

Case II.

Fig. 4 shows a dish-shaped adenocarcinoma on the prepyloric lesser curvature (histologically, ulcerating carcinoma). The patient, a female aged 44, had suffered from griping pain and tenderness over the epigastrium for four months. Another observer had interpreted the appearance as ulcer niche. My own diagnosis was crateriform carcinoma. The decisive point, to my mind, was the recognition of angular projecting ledges on the film proximal to the pylorus and at the angulus (arrowed). These ledges are really typical of a carcinomatous filling defect, whereas ulcer shows smoothly concave semicircular contours on the edges of the mucosal swelling which surrounds the niche.

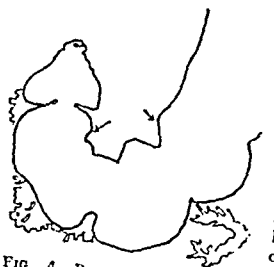

Fig. 4.—Prepyloric carcinoma on lesser curvature with crater and marginal ledges.

On the other hand, a shadow projecting into a filling defect signifies carcinoma. Fig. 5 relates to a still smaller carcinoma.

Case III.

The patient was a woman of 40, of healthy appearance, well nourished, with slight symptoms of over six months' duration. An *x*-ray examination by another observer six months previously had shown a suspicious region proximal to the pylorus, of uncertain significance, which disappeared after atropine.

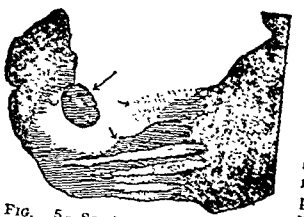

Fig. 5.—Small prepyloric carcinoma, with surrounding wall of infiltration. The rugae are interrupted at the edge of the zone surrounding the central barium deposit

X-ray Findings.—Stomach of normal size; moderate peristalsis; greater curvature of normal outline; near the pylorus is a bean-sized transversely oval dense shadow with a fairly sharply defined outline on all sides, which lies within a filling defect; this filling defect remains constant in the erect and prone positions. The mucous folds proximal to the filling defect shows an indistinct outline against the surrounding barium. In the supine position the mucous folds proximal to the defect are clearly seen to terminate abruptly (Fig. 5). No resistance. No tender pressure point. The duodenum fills normally. The bulb has regular contours; its medial recess is partly covered by the prepyloric barium mass. My interpretation is: Not ulcer, but a small carcinoma just proximal to the pylorus, with a deep crater. The decisive point in the diagnosis is the abrupt termination of the longitudinal folds about a finger-breadth from a central sharply defined barium deposit, and the clear rim surrounding the deposit as a constant filling defect. The deposit was not interpreted as an ulcer niche in spite of its well-defined outline.

Macroscopic examination of the resected specimen also in favour of ulcer, showing a flat dish-shaped crater, the size of half a hazel-nut, within an indurated area of small extent.

Histological Report: Strongly infiltrating carcinoma with deep ulceration.

Two years after the operation the patient is free from symptoms and in perfect health.

It is worth observing that the radiological interpretation of the changes as being due to carcinoma were even more accurate than the macroscopic examination of the resected specimen, at which it was assumed to be ulcer.

A small easily operable *scirrhus* is shown in Fig. 6. Circumscribed scirrhus almost always originates on the lesser curvature just proximal to the pylorus. Its pathognomonic feature is a "spigot" formation. The spigot lies on the lesser curvature, since the flat tumour of a fibrous nature with relatively few cells narrows the lumen by drawing the greater curvature towards the lesser. The stomach wall is therefore free from tumour at the point where it suddenly turns towards the lumen.

Fig. 6.—Small prepyloric scirrhus on lesser curvature. The characteristic point is the indrawing of a broad segment of intact greater curvature toward the lesser (arrows).

In prepyloric ulcer and benign thickenings of the gastric wall the lesser curvature is flattened, the convexity of the greater curvature maintained. The narrowed strip of shadow is therefore eccentrically placed in the opposite sense to what occurs in scirrhus (Fig. 7).

Medullary carcinoma offers the best chances for correct radiological diagnosis, for palpation, and for operation. Even when situated high up it is still quite resectable, because the stomach, having no tendency to shrink, retains its normal shape and mobility. Small medullary carcinomata show a central filling defect, like benign tumours—adenoma, fibroma, etc.—except that in these cases pedunculation and a well-defined edge of the filling defect may reveal their benign nature.

Fig. 8 refers to a tumour which was recognized as benign and consisted of several fibro-adenomata up to cherry size (operative confirmation). It is never possible to diagnose the benign nature of a tumour with complete assurance—first, because the differential diagnosis is not quite certain; secondly, because malignant degeneration not uncommonly occurs in a benign tumour.

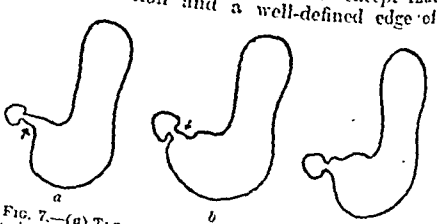

Fig. 7.—(*a*) Typical of prepyloric scirrhus. The barium shadow lies along the lesser curvature. (*b*) Typical of benign narrowing. The barium shadow lies along the greater curvature. (*c*) Upward convexity of lesser curvature bending due to pressure or traction.

Wechselmann[8] estimates that carcinomatous degeneration occurs in possibly 60 per cent. of all adenomata. Konjetzny[7] actually states that the majority of gastric carcinomata originate from adenomata and polypi, or at all events from an adenomatous precancerous stage.

The expert radiologist should therefore never assume the responsibility of having delayed a suggested operation, but should be prepared to accept the reproach of having supported rather than opposed an operation in a doubtful case. In my department a case of prepyloric polypi was watched for three years, and gradually began to show signs of malignant degeneration—namely, progressive growth and increasing loss of definition of the contours. Operation was continually refused by the patient, who had only slight symptoms. At the necropsy a carcinomatous degeneration of the tumour was found, which still retained a recognizable polypoid character.

FIG. 8.—Prepyloric fibro-adenoma resembling a commencing medullary carcinoma.

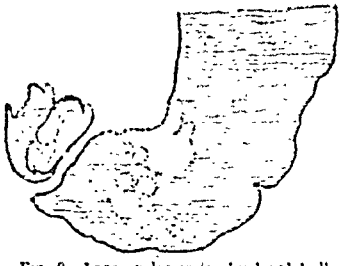

FIG. 9.—Large polypus in duodenal bulb. Small polypi in pars pylorica. (The translucent area at angulus was caused by compression.)

According to the foregoing conception the early diagnosis of adeno-carcinoma and medullary carcinoma is to some extent bound up with the early diagnosis of adenoma, fibroma, and polypi. How *small* a polypus can be detected by *x*-ray examination is seen by reference to Fig. 9. A date-sized polypus was situated close to the pylorus and was invaginated into the duodenum, as the operation proved. The radiogram clearly showed three translucent areas from linseed to pea size, arranged in clover-leaf fashion, which corresponded to polypi of exactly this size.

The early diagnosis of tumours of the upper part of the stomach, inaccessible to operation on account of their position, is, unfortunately, merely of diagnostic and prognostic importance, and does not affect their treatment. The same is true at the present time of cancers of the oesophagus and cardia.

CASE IV.

A commencing carcinoma of the ulcerating adenocarcinoma type is shown in Fig. 10. The changes could only be clearly recognized in the *partly filled stomach*, and the differential diagnosis from ulcer was by no means certain. With complete filling (Fig. 11) the stomach appears normal. The contrast between these two pictures proves how utterly inadmissible it is to make the first examination *after the patient has drunk the entire meal*. There was no operation, and the patient died fourteen months after the first examination.

FIG. 10.—Commencing adeno-carcinoma high up in body of stomach. In the *partly filled* stomach it is clearly visible.

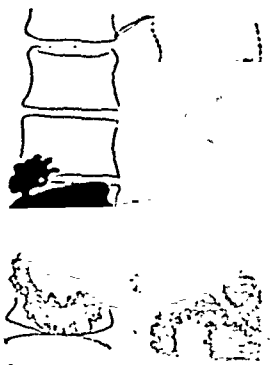

FIG. 11.—Same case as Fig. 10, stomach *completely filled*: stomach, to all appearance normal.

If we are right in our opinion that gastric carcinoma is recognizable in an early stage, then negative *x*-ray findings, denying the presence of a suspected carcinoma, must also be considered reliable. It has for many years been my experience that an exploratory laparotomy is not made when I have given a negative report, though a control by laparotomy would be a welcome event to me personally. Such a measure of trust, however, connotes no small personal responsibility, and I consider it my bounden duty to test the accuracy of my negative findings. For this purpose I use a rubber stamp which adds to the report the words, "If further clinical observation does *not* confirm the *x*-ray findings, please inform me."

In operation cases I only ask for information or (in hospital) an invitation to attend when the operative findings do *not* appear to agree with the *x*-ray report. A further method of precaution is to call up again those patients in whom a decision as to the cause of the symptoms can only be made by re-examination.

With this system of checking results not a single case has come to my knowledge in the post-war period in which, after I have excluded carcinoma in a clinically suspicious case, gastric carcinoma has eventually been shown to exist, either by operation or by the further course of the disease.

The only exploratory laparotomy made in recent years, in spite of a denial by me that cancer was present, was performed in the following case.

CASE V.

In a man of 73, with vomiting, wasting, and cachectic appearance, another observer had made an *x*-ray diagnosis of carcinoma of the body of the stomach. I found no carcinoma, only an organic cascade stomach with adhesions of the anterior stomach wall to the belly wall. As he was feeling very ill the patient himself wished to have the operation which had previously been recommended to him.

I attended the laparotomy. On opening the abdomen the surgeon found extensive adhesions, especially in the gall-bladder region. The gall-bladder was small, shrunken, and full of stones. The stomach was completely free from carcinoma, but *adherent in front*. Death occurred within twenty-four hours with severe cardio-vascular symptoms.

Cause of death: advanced arterio-sclerosis.

I now come to the erroneous positive diagnosis of early carcinoma. The more pain-taking the endeavours to show that a slight variation from the normal is due to a small carcinoma, the greater the risk of a wrong diagnosis in the positive sense—that is, *of diagnosing a carcinoma when none is present*.

As far as I know I have not myself fallen into this particular kind of error in latter years. It is true that I could *not* in all cases find with any certainty whether the case was ulcer or growth; yet I hold that it is possible in the majority of cases to distinguish a carcinoma crater from an ulcer niche. To avoid the horns of the dilemma by using the hybrid term "tumour niche" is, I consider, quite unjustifiable. I gave detailed reasons for this point of view some years ago in the *Fortschritte auf dem Gebiete der Rontgenstrahlen*,[9] stating precisely the points in the differential diagnosis.

In my consulting practice I most frequently see erroneous positive diagnosis of carcinoma in the pars prepylorica. I, too, have found myself face to face with the problem—in many cases extremely difficult, in a few cases insoluble—of distinguishing between a benign and a malignant lesion in this region. The reason is this: the prepyloric segment is the most frequent site of carcinoma—about 80 per cent. of carcinomata start here. Ulcers are certainly least commonly found here—occurring in about the proportion of 1 to 10 as compared with ulcers of the pars media. But the relatively small number of ulcers which occur in this region have three peculiarities which complicate the differential diagnosis: (1) They show "niches" less frequently than in other situations. (2) These ulcers are associated with more pronounced submucous oedema, with an increased tendency to spasm of the gastric musculature, and a greater degree of mucous membrane swelling. As a

part of the stomach is quite
, giving appea. illustrative in this con-
ng case (Case vi)

of the pylor ances similar to carcinoma.

CASE VI.—ered for four years from
n a young man of 21, who had suf in standing and prone
acidity, the x-ray photograph showe gent with a defect with
positions a narrowing of the prepyloric segm
blurred outlines on both curvatures
(Fig. 12). The appearances in them-
selves necessarily suggested car-
cinoma. The patient's healthy appear-
ance, his youth, the duration of the
symptoms, and increased acidity were
against carcinoma. On clinical grounds
a benign condition had therefore to
be diagnosed, in spite of the x-ray
appearances. And so I decided that
it might well be a case of several
ulcers close together. The operation
confirmed this. A barium cast of the
resected specimen corresponded exactly
with the radiogram taken before the
operation. A marked submucous
oedema (rather uncommon) around two
ulcers had caused the shadow defect.
One surgical authority (Jedlicka) has emphasized the liability of
prepyloric ulcers to submucous oedema.

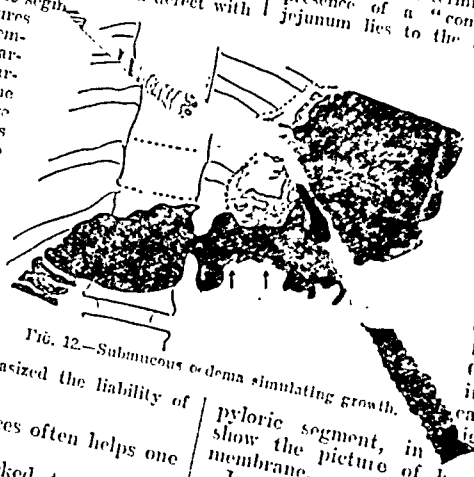

FIG. 12.—Submucous oedema simulating growth.

A very exact analysis of the appearances often helps one to a correct conclusion, but not always.

(3) The third peculiarity is the marked tendency of prepyloric ulcers to malignant degeneration.

My own experience agrees with the facts established by Orator[9] on material from the Eiselsberg Clinic, that about one-third of prepyloric ulcers undergo cancerous degeneration, but only 3 per cent. of ulcers of the pars media, and hardly ever a duodenal ulcer. The difficult differential diagnosis and the tendency to malignant degeneration are sound reasons for recommending operation in prepyloric ulcer.

The diagnosis of these ulcers is in a certain sense a contribution to the early diagnosis of gastric carcinoma. Early recognition of malignant degeneration of ulcer is really the province of the histological investigation, and extremely unreliable by x-ray investigation.

Even when there is no peptic ulcer, conditions simulating carcinoma may occur in the prepyloric segment caused by non-malignant thickening and contractions of the wall. Regional gastrospasm, the cause of which is still unexplained, circumscribed fibromatosis—linitis plastica—and gastric syphilis must be mentioned in this connexion. Atropine and papaverin usually fail to overcome the condition of spasm. Only by the fact that the course of the disease does not correspond with that of cancer, or by the presence of normal acidity, is the benign character of the disease occasionally recognized in these rare conditions.

In case of doubt one will never dare to put off recourse to operation. On these and other still slighter deformities of a harmless nature which alter the prepyloric segment by tapering it to a point and bending it, and may therefore add to the difficulties of early diagnosis of scirrhus, I have already reported at Stockholm.[10] I give here an instance of one from the group of cases just mentioned.

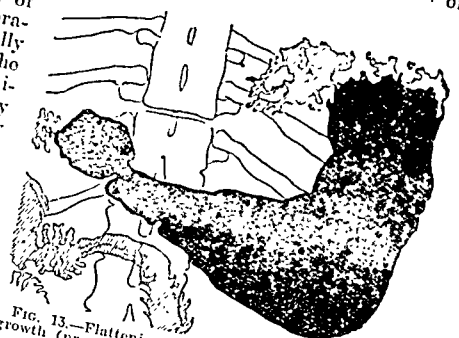

FIG. 13.—Flattening of lesser curvature simulating growth (prone position).

CASE VII.

In a doctor of 40 a narrowing of the prepyloric region, shown in Fig. 13 (prone) and in Fig. 14 (erect), had been interpreted by another observer as scirrhus, and resection of the stomach had been advised. I considered the narrowing to be due to a benign condition, as the longitudinal prepyloric folds were present in the erect position (arrow, Fig. 14), and in the prone position the eccentricity of the small prepyloric barium mass is clearly seen to be towards the greater curvature side. The fine indentation is merely due to thickened mucosa. Peristalsis in the prone position is normal. I determined the cause of the abnormality to be the presence of a "common mesentery," in which condition the jejunum lies to the right of the stomach, and the caecum lies in the mid-abdominal region. On the strength of my findings no operation was performed.

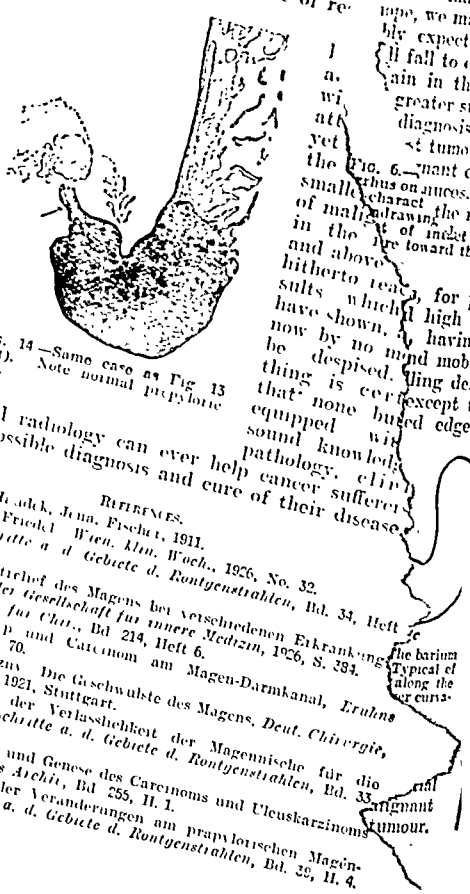

FIG. 14.—Same case as Fig. 13 (erect). Note normal prepyloric rugae.

I should like to say something in conclusion on the *significance of gastritis in the early diagnosis of gastric carcinoma.*

The difference between the gastritis in patients with ulcer and gastritis in patients with carcinoma is the subject of increasing comment in surgical and pathological literature. According to Orator, the inflammatory changes in ulcer are confined to the pyloric segment, in cancer they are generalized and show the picture of high-grade atrophy of the mucous membrane.

In ulcers which had become carcinomatous, as proved by histological examination, Orator found, in the majority of cases, the pyloric gastritis characteristic of ulcer, in contradistinction to the cases of true carcinoma.

If the claim, put forward with [illegible] that it is possible anatomically to distinguish a precancerous gastritis from a gastritis associated with predisposition to ulcer—then be eventually established—namely, that the question that the Konjetzny would be justified in his suggestion that the study of the resection of the precancerous gastritis represents the early operation on a carcinoma. In this case the study of the gastritis would relief pattern of the mucous membrane search. offer an extremely promising line of research.

We may fairly hope, we may reasonably expect, that it will fall to our lot to attain in the future greater success in the diagnosis of the yet [illegible] tumours and

FIG. 6.—[illegible]mant changes [illegible]rbus on mucosa, other [illegible] smaller character the point [illegible]drawing of malignant [illegible] of indent gres in the [illegible]re toward the l

and above hitherto teac[illegible], for pa[illegible] sults which high up have shown, having now by no mind mobili[illegible] be despised. [illegible]ling defec[illegible] thing is cer[illegible] except th[illegible] that none bu[illegible] edge of equipped wi[illegible] sound knowl[illegible] pathology, clin[illegible] medicine, and radiology can ever help cancer sufferers the earliest possible diagnosis and cure of their disease.

THE VALUE OF PHYSIOLOGICAL TESTS OF RENAL FUNCTION.*

BY

E. B. VERNEY, M.A., M.B., F.R.C.P.,

PROFESSOR OF PHARMACOLOGY, UNIVERSITY COLLEGE, LONDON.

THROUGH the employment of the tests of renal function I presume that it is sought to determine the manner in which the kidney responds to a stimulus superimposed upon that which it is already receiving, and that the hope is entertained of interpreting this response in terms of renal reserve. I propose, therefore, to confine my remarks to some considerations based partly on experimental fact, partly on theory and analogy, as to the manner in which the kidney, endowed with varying degrees of renal reserve, responds on the one hand to an increase in the work which it is called upon to perform, and on the other hand to a diminution in its functional capacity. The assessment of the value of the many tests which have been introduced to prove the functional capacity of the kidney I shall leave to speakers whose experience in their use has been much wider than my own.

It is essential, therefore, that we should first attempt to form some picture of the reserves of the kidney. They may be divided into those of a structural and those of a functional nature. The former are represented by a large excess of renal tissue over and above that competent alone to carry on the excretory work demanded during resting metabolism. The latter are represented by an inherent and variable capacity exhibited by any given amount of renal substance for the performance, under an adequate increment of stimulus, of an increased amount of work. Let us pursue this question a little further. The architecture of the kidney, as Bowman clearly recognized and described, is repetitive in character, and the functional response of the whole kidney at any time is the integral of the responses of the individual units of which the kidney is composed. The number of such units in a human kidney is 4.5×10^6, so that the normal man is provided with roughly ten million units, each potentially capable of supplying its quota of fully formed urine. That such an enormous number represents a considerable reserve of secretory tissue is indicated by the results of the experiments of Richards and his colleagues. Richards has shown by direct observation of the glomerular tufts of the frog's kidney that the number of active glomeruli—that is, those through which a flow of blood is visible—varies continuously, and that the number of active glomeruli in a given field can be increased by injection of diuretic substances and diminished by injection of vaso-constrictor substances. Each unit passes through alternate periods of rest and activity, and, as we should perhaps expect, these interruptions are not regular in occurrence and do not affect all the glomeruli within a single field at the same time. The number of units is so large that it is possible for the kidney as a whole to function efficiently under normal conditions when each unit comprising it works for a fraction only of its time. Such experiments give us a clearer insight into the meaning of the term "reserve of the kidney," since clearly, when increased work is called for, more units may be mobilized, and the units themselves may respond either by increasing their intervals of work at the expense of their intervals of repose or by increasing the intensity of their work during their active periods. This alternation of activity and rest which the units of the kidney undergo may be looked upon as the concrete representation of its first line of defence against the inroads of disease, and of a part of its total capacity for dealing with an increased load of work. A simple increase in the secretory stimulus, or stimuli if these are different in nature or if each has a different seat at which it becomes effective, may be expected, therefore, to cause an increase in the output of urine by requisitioning units previously inactive, and by diminishing the rest pauses of the active units. It is not necessary to assume that such an increase would be necessarily accompanied by any change in the composition of the urine. As the work demanded of each unit increases still further its commencing failure will be reflected in a change in the composition of its secretion—a change which exhibits an approach towards the composition of the blood plasma. Such a change is seen in the polyuria of chronic nephritis, and is the expression of the involvement of the functional reserves of the units, as contrasted with that of the anatomical reserves of the kidney to which attention has just been directed. This functional change is probably initiated by a local increase in the pressure stimulus—namely, the glomerular capillary pressure—and it may be instructive to compare such a change with that occurring in the heart when its load of work is increased.

When the heart of the dog is isolated and disposed in such a manner that the blood entering the right side of the heart is ejected by the left ventricle against a measurable and variable resistance—the heart-lung preparation of the late Professor Starling—it is possible to vary at will the amount of work performed by it. As the heart tires under a constant load, or if it is given more work to do, it dilates, and we speak of this dilatation as an indication of partial failure. Its "tone" is diminished and its functional reserves are dwindling. An analogous state of affairs is found in the case of the kidney. Here, however, the work performed is osmotic in character, and the sign of failure on the part of the kidney is an approach in the composition of the urine towards that of the blood plasma. Obviously, if the composition of the urine were the same as that of the plasma, no energy would be expended in its formation. And since the osmotic pressure of the protein fraction of the plasma is so very small any work involved in its separation is negligible. We may state therefore with accuracy that a kidney which is engaged in producing a urine having the same composition as the protein-free filtrate of the blood plasma is doing no work; failure is complete. Any degree of approach, then, in the composition of the urine to that of the plasma is a sign of renal failure, and in this respect is analogous to dilatation in the case of the heart.

We may, indeed, press the analogy still further. We have already referred to the fact that the heart responds, by dilatation, in two main conditions—first, when its tone is diminishing under a constant output of work, and, secondly, when an increase in the work performed is demanded of it. Likewise, the kidney responds in two main conditions by secreting a urine the composition of which moves towards that of the plasma—first, when its tone is diminishing under a constant stimulus, and secondly, when an increase in the stimulus to secretion is effected. This stimulus, upon which the function of urine secretion by the kidney is absolutely dependent, is in all probability the glomerular capillary pressure, and it is perhaps not stretching analogy too far in drawing a functional comparison between the glomerular capillary pressure and the right auricular pressure. By definition, then, if two kidneys, each having the same amount of functioning tissue, each being supplied with blood of the same composition, and each receiving the same pressure stimulus, secrete urines at the same rate but of different compositions, the reserve capacity for performing work of that kidney the composition of the urine from which more nearly approaches that of the blood plasma is smaller than that of the other kidney. But clearly such a definition is of no practical value in clinical medicine unless some means are available of measuring these reserves. We may summarize our knowledge of the reserves of the kidney as follows:

Anatomical reserve	Number of renal units in kidney.
Functional reserve	(Magnitude of pressure stimulus to secretion. ("Tone" of secretory unit.

A fall in the functional capacity of the kidney is to be regarded as being due to a diminution in one or more of these three factors. The fall may be explicable in terms of a diminution in the number of renal units, or in the magnitude of the pressure stimulus, or in terms of a diminution in the tone of the secretory units. It is of interest to observe that a relationship may be shown

* Read in opening a discussion in the Section of Physiology and Biochemistry at the Annual Meeting of the British Medical Association, Manchester, 1929

experimentally to exist between the first two factors. Rose Bradford demonstrated that a diminution in the amount of kidney substance led to an increase in the urine production by the remaining tissue, and it can be shown in the case of the isolated kidney of the dog that functional removal of a part of the kidney leads to an increased flow of urine from the remainder, and that this increase in urine flow is accompanied by just those changes in composition which occur when the perfusion pressure to the kidney is raised. A diminution in the anatomical reserves of the kidney is thus partially or completely compensated by an encroachment upon the functional reserves, in that the pressure stimulus to secretion becomes more effective, and polyuria of varying intensity results. This is of interest, since the excretion of urea and of substances eliminated by a similar mechanism is dependent mainly upon the amount of kidney substance, that of chloride mainly upon the rate of urine flow.

We may, then, recognize theoretically three main types of renal failure corresponding to the primary involvement of one of the reserve factors indicated above. That type, resulting from a severe diminution in the number of renal units, would be expected to be the most serious, since the disturbance could be rectified only by profuse regenerative changes. Renal failure resulting from a fall in the magnitude of the pressure stimulus or in the tone of the secretory units might well be of temporary duration and *susceptible to therapeutic intervention*. Is it possible that the *primary involvement* of each of these theoretical factors in the decrement of renal reserve has its clinical and pathological counterpart in polyuria with cirrhosis of the kidney, in oedema with parenchymatous nephritis, and in nephritis associated with toxaemia?

The three factors mentioned are possibly indissolubly involved in any given case of renal impairment, but their recognition may indicate the *principles upon which* any test of renal function should be based and the limitations to which its interpretation should subscribe. Since our present knowledge of the physiology of urine secretion suggests that the most important factors upon which the successful mobilization of the reserve of the kidney would seem to depend are the number of renal units and the pressure stimulus to secretion, a systematic investigation of the effects of some substances which, in the normal kidney, increase this number and pressure, might reasonably be supposed to give some indication of the magnitude of these reserves. Caffeine is such a substance. It was shown by Richards and his colleagues that this drug increased the number of active glomeruli in the frog's kidney, and it can be shown in the case of the isolated kidney of the dog that the increased flow of urine is explicable in terms of an increased effectiveness of the pressure stimulus. These facts suggest that the systematic employment of this drug under controlled conditions in nephritis might throw some light on the capacity of the kidney to perform extra work. A large response would point to a correspondingly large functional reserve, a small response to a small current reserve, which might or might not increase with the lapse of time. It will be of great interest to hear the experiences of members of this Association in the use of this drug, and their views as to the significance of the results obtained.

With regard to the employment of substances eliminated by the kidney as a test of renal function, it would seem that the surest indication would be given by the results of the administration of urea or other bodies eliminated by a similar mechanism, such as phenol red. And in this connexion it would seem advisable to take the amount eliminated over a given period of time at any given concentration of the substance in the blood plasma compared with that eliminated under similar conditions by the normal kidney as an index of the current reserves of the kidney. But the practical application of the present state of our knowledge of renal function and renal adaptation to the evolvement of methods of assessment of renal reserve is fraught with difficulty, and it should prove most instructive to hear from those who are interested in this problem which tests they employ and the interpretation they are inclined to place on the results obtained.

RADIUM TELETHERAPY:
CLINICAL EXPERIENCE WITH A TEMPORARY "BOMB."*

BY

E. ROCK CARLING, F.R.C.S.,
SURGEON TO WESTMINSTER HOSPITAL;

AND

A. J. LESLIE-SPINKS, M.A., B.M., CH.B.

WHEN it became possible to employ a gram of radium as one unit, at a distance from the skin of 10 cm., the staff of the Westminster Hospital (to *nine of whom we tender* thanks for permission to use their notes and cases) had already constant personal familiarity with interstitial and surface methods. This practical experience had taught, or driven home, lessons others had learned. First and foremost was the paramount importance of screenage; but there were also the capabilities of small total doses; the difficulty of gauging sensitivity, or regulating doses, by histological appearances; the diversity between immediate response, especially of primary growths, and ultimate prognosis; the difference in the *response of glandular metastases* from tumours themselves, not very dissimilar in their response at the primary site; the want of a reliable means of increasing, differentially, the sensitivity of cancer cells, or of influencing their metabolism; the conviction that cure of disseminated cancer must probably not be looked for *from local irradiation*.

Whilst, on the one hand, it was learned that a patient with advanced fixed fungating cancers of both breasts and extensive glandular metastases, seemingly near her end, might resume what appeared to be radiant health; on the other hand, a patient with a rapidly advancing cancer of the vulva and vagina, in the moment of satisfactory success as to her "growth," might die—of what? The necropsy supplied no answer, and the rest is speculation. It was found, as others had found before us, that anaemia was an inconstant factor, often amenable to control by administration of liver; that irradiation of the liver was accompanied by severe disturbance in the gastro-intestinal tract, and disorder of its own functions. As to the skin, it was known that, with exceptions, it was possible to steer clear of lasting injury, and that warnings, generally speaking, are timely. So far as it already burdens the lymphatic vessels and glands in relation to a growth, sepsis is a grave menace to success. Neuritis in the presence of sepsis about a nerve trunk, or actual invasion of the sheath by growth, is to be feared even with well-screened radium; and particularly in the case of the mouth and jaw.

On commencing work with a provisional teletherapy apparatus, it was not entirely an advance into an unexplored field—partly because others had been there long before us, partly because interstitial methods inevitably involve irradiation of the tissues surrounding the mass in which needles were implanted, and at least no obvious harm has come, in our cases, from screened rays reaching the tissues of and round the uterus and rectum, the colon, the breast, the cervical glands, and other parts. In teletherapy, however, unless very narrow beams can be directed with great accuracy on a growth, important structures, such as the heart, the spleen, the liver, the ovaries, the bone marrow, the thyroid, the thymus, and so on, must at times be irradiated. Always there must be a considerable intensity, and a considerable dose, of irradiation upon subcutaneous and more important intervening tissues. In cases treated by teletherapy the element of infective oedema is generally absent, but in local extensions the lymphatics are often blocked, and it is to reach infiltrating extensions, as well as primary growths difficult of access, or visceral metastases, that the method lends itself.

As to the difficulty of obtaining a valid intensity at the depths required for visceral growths, a preliminary physical inquiry could start from the observation that when certain growths were needled, notwithstanding an irradiation

* Sequel to the article by Francis Rock Carling, B.Sc., published in the *British Medical Journal*, May 11th, 1929, p. 845.

inadequate from the physical point of view as to homogeneity, yet the whole tumour would disappear. Clearly, then, a dose and an intensity inferior to that aimed at and striven for must sometimes be effective. Why? Because the dose needed had been overestimated? because the secondary radiations were more potent than had been believed? because an effective alteration of the metabolism of the great mass of the growth could effect, in the same sense, the adjacent imperfectly changed cells? or because the healthy cells surrounding were no longer overwhelmed into defencelessness? or because of reasons too fanciful to put to paper?

It is true that Regaud, Failla, Sluys, and Cheval have employed very large amounts of radium in their bombs, but Forsell, Malet, Perussia, and others use amounts of less than the gram we had available. To look up one gram of radium (to say nothing of three or four) in an apparatus, even one giving a twenty-four hours' service, requires some justification. It is very satisfactory, with needles and seeds, to see a primary growth disappear, and to be able sometimes to banish signs of glandular implication. Many patients are thus rid of an intolerable discomfort or disability, or of evidence, such as a discharge or a lump, that affects their minds; but while the patient may thus be spared suffering and anxiety, the surgeon is not freed from gloomy forebodings, and constantly meets severe disappointment. Patient after patient, free from the primary lesion, comes back with visceral metastases, perhaps with fresh evidence in the lymphatic glands, occasionally with recurrence in, or immediately adjacent to, the primary site. Either the dose was insufficient in intensity or in extent, or lacking in homogeneity, or too short in duration, or too intense, or too long, or the spacing of the exposures was wrongly timed. Inevitably the need arises for some means of reaching the visceral deposits; of covering a whole lymphatic field uniformly; as well as some other means of dealing primarily with growths from the out-set unsuitable for needling.

The teletherapy apparatus in a general hospital is a means of treating patients, and only in a secondary sense a method of investigation of the powers of radium so applied.

It is difficult to make selection of a particular type of growth or of particular stages in its progress; it is not possible to restrict treatment to teletherapy alone; men and women present themselves for relief in the hope of cure, often when their vital powers are already grossly impaired, and hitherto none have been rejected who were not obviously dying. The patients so far treated have been those with growths that do not lend themselves to any other form of radium application: those with growths which clearly need something in addition to interstitial, cavitary, or surface treatment; those with growths which by their volume and extent preclude homogeneous irradiation by local methods; and those who, having been treated surgically, receive prophylactic irradiation. The great majority of the patients would be classed as hopeless, and a number were already within sight of the grave.

It is difficult to envisage radiation as "curing" cancer in any other manner than through normal physiological processes of defence or repair, rejuvenation, or restitution. Radium might be employed merely to necrose the malignant cells, but the cautery, escharotics, coagulation, or the knife are cheaper, safer, and less uncertain. The energy from screened radium supplying all but pure gamma rays is actually very small in quantity, and of that more reaches the normal tissues than the growth, except in very favourable anatomical circumstances. Can we believe that all the benefit is derived from action on the cancer cell? Is not a part due to beneficial action on cells of the invaded tissues—if not on more distant units? The work of Dominici as far back as 1909 already suggested that that might be the case.

Perhaps, then, the energy received by the tissues surrounding a growth, when the cone or cones of rays from a "bomb" cannot be accurately adapted to the exact contour of the tumour, far from being wasted, may prove of great value.

Our notions of dosage, though based upon experience with interstitial and surface work, have been purely empirical. Forsell and others have discovered certain general truths—as, for example, that "a certain minimum of absorbed irradiation in a given time is necessary to secure healing of a given type of tumour," but it is as yet far from easy to measure the amount absorbed; that certain maxima must not be exceeded if the whole organism is not to be damaged; that, other things being equal, the dose should be as concentrated, as to time, as may be, to minimize the duration of exposure to metastasis; and that an interval should not be so long as to give opportunity for the malignant process to re-establish itself. It is difficult, however, to translate these principles into figures. In the first place it was necessary to ascertain what dose the skin would stand with impunity in the conditions—a gram of radium at 10 cm. distance—so that the dose possible through one port of entry might be known. So far 50 gram hours have resulted at the worst in a slight pigmentation of the skin with a trifling alteration of texture; though the parts do not pit, the skin has lost a little suppleness as if slightly swollen. The brownness does not persist more than a week or two, and no loss, even of epidermis, has resulted. With, say, four ports of entry then 200 gram hours may be given without danger; but in the circumstances of our present use of the bomb it is rarely possible to give more than four hours a day, and this means a month's treatment, for ordinarily the radium staff are deliberately excluded from the premises on Sundays. Clinical experience quickly showed that the dose possible, under the conditions concerned, for deeply seated small tumours, such as a carcinoma of the oesophagus and of the bronchus, was inadequate. This agreed with calculation. On the other hand, growths such as carcinomata of the pyriform fossa proved susceptible and showed early changes, with great betterment; but there the short distance beneath the skin surface makes a much greater intensity possible. No ill effect on cartilage has been observed. Dosage has actually varied from 12 to 150 gram hours.

The first fifty cases treated have been:

Carcinoma.	
Larynx	3
Pharynx	4
Tongue and mouth (extensions)	4
Oesophagus	2
Ovary	2
Cervix	3
Vulva	2
Renal	4
Breast (recurrences and metastases)	5
Testicle (multiple metastases)	1
Prostate, parotid, lung, rectum, and colon—one each	5
Sarcoma.	
Of bone	4
Other	8
Cerebral tumours	3
	50

Taking these by classes it may be said of:

(1) The tongue and mouth cases treated for local or glandular extensions, that they have done badly, they were in any case the hopeless failures of other methods. There has been temporary improvement, but the effect has been limited to slight delay in downward progress.

(2) The larynx and pharynx cases have been the most satisfactory; they hold out definite hopes of success when the best dosage has been ascertained.

(3) The oesophagus is beyond our range unless the post-cricoid growth be included, but it belongs in this respect to the previous group.

(4) The uterine and ovarian cases were failures, but were all the subject of extensive abdominal invasion.

(5) Of the renal cases the same must be said—the results are merely palliative.

(6) Breast recurrences can be kept in check, even when very extensive, but previous deep *x*-ray therapy may be a formidable handicap.

(7) Vulval glandular extensions do not prove nearly so sensitive as the primary growth.

(8) Osteogenetic sarcomata have not shown more than quite temporary recession; other round- and spindle-celled growths are more promising.

A few sample cases may be briefly mentioned.

Case 1.—An instructive case of epithelioma of the whole area of the buccal surface of the left cheek, invading the lower and upper alveolar borders back to their junction. A mass of growth was protruding upon the skin surface covered only by a thin pellicle. After twenty-five hours' exposure the lump had disappeared, and was represented by a deep dimple; the skin surface of the cheek, slightly browned and a little inelastic, was intact over the whole area. It was then possible to give a cavitary treatment to the ulcerated mucosal surface, and all appeared well, but in less than a month—and one week after an injection of DHS—a new "lump" appeared beneath the skin close to the original fungation, and a hard mass, rapidly growing at the angle of the jaw involving the masseter, as well as enlarged cervical glands.

The first response was remarkable; not only did the fungating mass disappear, but the normal dermal tissues were re-formed. Why, then, the sudden re-emergence? One possibility is that the cavitary dose upon the top of the teletherapy damaged the stroma and vascular apparatus and permitted surviving lethargic cancer cells to regain dominance. Another is that it was wrong to administer lead just at that stage. Two other cases suggest the inadvisability of approximating lead injections too closely to irradiation. Cheek epithelioma, however, is notoriously difficult to treat satisfactorily by any means, except in quite early stages.

Cases 2 and 3: Retroperitoneal Sarcoma.—These two cases, one a known subject of endothelioma of lymphatic glands, who by operation and medium *x*-ray therapy for other regions has been kept alive for three years, came back with a large retroperitoneal tumour in the epigastrium; the other, a retroperitoneal tumour disclosed at operation, believed to be a lymphosarcoma (but without biopsy). Both proved radio-sensitive. In the one case the mass disappeared after 40 gram hours; in the other it was reduced to less than one-third its size forthwith, but shows a tendency to enlarge again and again when treatment is stopped. The latter patient feels so well, in general health, that it is very difficult to persuade her to spend the necessary time and trouble in coming to the hospital for treatment. She has had 100 gram hours.

Case 4.—This case was one of an immense and bleeding round-celled sarcoma of the neck, filling the space from acromion to mastoid, the patient being in a desperate state of cachexia with anaemia, dyspnoea, and dysphagia. Under treatment by radon and surface appliance, with certain heavy metal injections, the mass was reduced to a thick induration covered with skin. After six months nodules began to appear in the skin, and teletherapy was begun. The general condition of the patient has been well maintained at the high level attained after the original treatment, and the cutaneous masses, though they have not disappeared, have diminished in size. There is no evidence of visceral metastases. A slight loss of weight seems to be of no particular significance.

Case 5.—A case (under the care of Mr. Stanford Cade) of metastases (in the liver and elsewhere) from carcinoma of the breast. The patient received 18,000 mg. hours in the hepatic region, but the treatment had to be discontinued, and death occurred soon after cessation. In this case, certainly, liver function was already seriously impaired by actual destruction, and direct irradiation added to the effect.

Case 6.—A case of extensive metastases from carcinoma of the left breast, in the right breast, chest wall, pleura, left axillary, and supraclavicular glands, which failed to yield to interstitial treatment and received no surface application. "Bomb" treatment was followed by immediate ease, cessation of pain, and remarkable return of well-being, lasting, however, only a few hours after each application. Final result not yet known (June 20th).

Case 7.—This patient (under the care of Mr. Chubb), suffering from post-cricoid carcinoma, was quite unable to swallow, was too weak to get out of bed, and weighed only 4 st. 10 lb. After insertion of radon in January, 1929, she began teletherapy on March 9th, and has received so far 110 gram hours. She is well, runs about briskly, weighs nearly 7 st., and, beyond a slight hoarseness, seems quite well (June 20th).

Case 8.—This patient (under the care of Mr. Arthur Evans) had carcinoma of the larynx with very large fixed glands in the neck; after 700 mg. hours interstitially for the glands, he received 38,000 by teletherapy. The laryngeal growth disappeared, and his general condition, which was grave, has improved so remarkably that, although now (June 20th) he has a pedunculated recurrence from the right cord, he declares himself very well indeed.

Case 9.—This patient (under the care of Mr. Stanford Cade), a case of carcinoma of the pyriform fossa, has made a striking recovery, and will be, with other similar cases, the subject of a special report by Mr. Cade.

An important result in general has been relief from pain. It is not always maintained, especially in cases involving bone. Some of the ameliorative effects of irradiation may be immediate; betterment as to pain and discomfort often surprises by its rapid occurrence. Perhaps it is only a psychological effect, but it is grateful, nevertheless, to the sufferer, and often persists longer than would be expected if purely psychological. Appetite is often improved, but where the liver is involved or suffers, nausea and vomiting may interfere with the taking of food. Whilst most patients experience a grateful wellbeing, some suffer from serious depression, which, however, is only temporary if progress is made. Sleep is nearly improved, many patients sleeping undisturbed while in position on the apparatus. Ten patients have died during the six months.

CAUSES OF USELESS.

Insufficiency of irradiation intensity; wrong or improperly spaced dosage. Harmful effects upon the blood and haemopoietic system, necessitating cessation of treatment. Depression of function of glands, liver, kidney, thyroid, and pancreas, with deterioration of general health. These are the subject, at present, of special investigation by Dr. F. D. M. Hocking.

The effect upon the blood seems to differ slightly in carcinoma and sarcoma cases. In the latter the red count may increase, with a slight falling off of the white cells. In the former the red count falls, but the haemoglobin decreases less, so that the colour index tends to rise. The quantity of urine passed during the period of irradiation is diminished—a consideration of importance in connexion with the blood estimations.

When the first fifty cases so far treated are reviewed, what can be said of the effects?

The many very advanced cases have not gained materially, and in one or two instances the surgeon in charge has noted the impression that the neoplastic process has been hastened. There is, however, no proof that its development has been more rapid than the terminal rush downhill often seen in such cases apart from irradiation. That the effects of irradiation are purely local is evidenced by the steady march, even whilst one group of metastases is vanishing, of others beyond the field of irradiation.

The growths capable from their situation of receiving irradiation of high intensity have shown the best results—those, that is to say, in the pyriform fossa, the post-cricoid region, abdominal and cervical glands; but it must be remembered that the last group includes some that are susceptible of satisfactory treatment by *x* rays even of medium penetration.

For dealing with carcinoma and administering a dose of adequate intensity in a short enough time, there seems little doubt that the amount of radium necessary is greater than our present supply, and we have seen nothing to suggest that by greater intensity the organs or tissues will be seriously damaged. Modifications in our apparatus promise us greater efficiency, but we need at least another gram.

So long as the amount available is no more than a gram, it will probably be advisable to restrict its curative use to cases of carcinoma at a depth not greater than 6 cm. Very susceptible tumours may more cheaply be treated by *x* rays. Prophylactic use after surgical operation seems well warranted. Preliminary treatment in cases of doubtful operability should also be tried.

The following note on radium teletherapy is by Mr. Leslie-Spinks, who has personally made the majority of adjustments of patients for treatment.

Note by A. J. LESLIE-SPINKS, M.A., B.M., Ch.B.

The structure and mechanism of the temporary "bomb" in use at Westminster Hospital has already been described in a previous paper (vide *British Medical Journal*, May 11th), but perhaps some account of the routine followed in its use may be of interest. Before any patient is treated with this apparatus a drawing is made to scale of the lesion and its situation in the body, and an intensity chart is applied to this drawing. By means of this chart the intensity of irradiation at the growth when approached from various ports of entry can be ascertained, and the best way of treating the growth decided upon. Though the calculations are made for conditions in which the source of irradiation is at a distance of 10 cm., yet with the apparatus at our disposal it has been necessary, in many cases, for purely mechanical and anatomical reasons, considerably to exceed this focal distance, with the result that the intensity actually received at the lesion has been much

diminished. This fact may in part account for our lack of successful results in some cases. In the permanent apparatus now under consideration measures are being taken to overcome this difficulty. The results obtained in those cases (for example, intra-abdominal or mammary or cutaneous neoplasms) in which the lesion is accessible to the full intensity have been so much more favourable than in those in which, either for anatomical reasons or on account of the patient's comfort, the distance has had to be increased, that it would appear that a smaller apparatus is necessary for dealing with some lesions.

The "bomb" is in use continuously for twenty-four hours daily for six days each week. During the day out-patients are treated, and during the night in-patients, the average time given to each case being two hours. It has been found that most patients are very nervous during their first period of treatment; but that on the second and subsequent occasions they are quite reassured and comfortable. The majority of our patients sleep quite peacefully, and say that their sense of comfort and well-being is increased while they are on the "bomb" and for some time afterwards. Thus it is no great hardship for the patients to leave their beds in the wards and go to the "bomb" at night. Two patients have even said—and it has been confirmed—that they slept better while having their treatment than when in bed in the ward.

When the patient is put on the stretcher the "bomb" is adjusted as near as possible to the correct focal distance at the port of entry decided upon, the patient is made comfortable, and in the majority of cases falls asleep in a short time. The ports of entry are changed on alternate days, and in this way not only is the danger—and this is apparently very slight—of damage to the skin minimized, but the intensity at the growth is increased.

Periodical examinations of the blood are carried out, as are tests of liver function and other biological tests, and in this way the effects of irradiation on the organism as a whole are controlled. A register is kept and discussed at a weekly meeting of the staff, at which the past week's results are examined and the programme for the succeeding week is decided upon.

SPINOCAIN: THE CONTROLLABLE SPINAL ANAESTHETIC.*

BY

GEORGE P. PITKIN, M.D., F.A.C.S.,

CHIEF SURGEON, HOLY NAME HOSPITAL, TEANECK, NEW JERSEY.

To discuss the clinical features of spinocain would seem somewhat far-fetched. Dr. Frank A. Kelly of the Grace Hospital, Detroit, Michigan, has worked with the solution from its early experimental days, and he, I believe, will gladly enlighten you as to its clinical advantages. With your permission I will endeavour to enumerate some of the theories we had concerning spinal anaesthesia and explain the reasons for our conclusions.

Since the introduction of painless surgery our dreams have been an ideal anaesthetic—one that would abolish pain completely, be reliable and certain in its action, constant in duration and intensity in direct ratio to the amount employed; one that would not alter the normal secretions of the body; one that would not affect respiration and circulation; one that would be free from all complications brought about by the action of inhalation anaesthesias, such as pulmonary oedema, bronchitis, pneumonia, lung abscess, acidosis, distension, ileus, acute circulatory failures, etc.; one that would not materially disturb the central nervous system. Such an anaesthetic should essentially be non-toxic, be simple of administration, lessen morbidity, and abolish anaesthetic mortality altogether. However, such an anaesthetic is still a dream. The reality is our present-day anaesthesia, the deleterious effects of which are an ever-growing concern of thoughtful surgeons.

The short time allotted to this paper does not permit going into the problem of the causes of anaesthetic morbidity and mortality. It should be pointed out, however, that the problem is a part of the great problem complex of cardio-respiratory physiology and pathology, that has remained largely unsolved to our very days.

However, we know that it is through their interference with the normal cardio-respiratory correlation that anaesthetics cause their ill effects. We see the phenomena of cardio-respiratory decompensation ensue as soon as the anaesthetic action reaches and depresses higher central nervous elements regulating respiration and circulation, regardless of whether the anaesthetic was inhaled through the lungs or injected into the subarachnoid space in a manner enabling it to diffuse in a cephalic direction. The respiratory embarrassment as manifested then in the degree of anoxaemia, or the circulatory collapse as manifested in the degree of hypotension, is in both cases directly proportionate to the action of the anaesthetic. The functions involve central nervous mechanisms upon which the effect of the anaesthetic varies greatly even from one individual to another; it is therefore beyond our power to estimate or control. In this lack of control lies the source of all complications of anaesthesia, caused by the anaesthetic, regardless of whether inhaled or injected. The action of the anaesthetic depends on its diffusion. To control diffusion of the anaesthetic thus becomes the paramount goal of all anaesthetists.

The fatalities of respiratory embarrassment or circulatory collapse at the time of operation, are not to be compared with the secondary mortality, which is 99 per cent. of the whole as compared to a scant 1 per cent. of a primary mortality. How many anaesthetists or surgeons can truthfully say that they have had 100 consecutive cases without some post-anaesthetic complication, such as shock, bronchitis, pneumonia, lung abscess, distension, ileus, acute cardiac or gastric dilatation, albuminuria, suppression, or acidosis; many or all of which may be directly attributable to a partial or impaired respiratory or circulatory dysfunction?

The surest method of eliminating anaesthetic complications is by the use of local or conduction anaesthesia. Unfortunately its art is not familiar to all of us, nor is the method adaptable for all operative procedures. But, with a combination of these and controllable spinal anaesthesia, any operative procedure may be carried out with greater protection to the patient and better facilities to the surgeon. To eliminate the possibility of respiratory and circulatory disturbance, permit me to suggest a spinal anaesthetic that will not diffuse with the spinal fluid, one that can, with the proper technique, be placed under the direct control of the operator.

As we have known spinal anaesthesia in the past it produces hypotension. In fact, so great is the circulatory depression that one well-known author in America states that "the radial pulse cannot be felt by the finger, nor can it be detected by the ear when the arm is subjected to the pressure of the cuff of the sphygmotonometer." This extreme drop in the blood pressure is due to diffusion of the anaesthetic fluid cephalically. If the anaesthetic fluid is confined to the lumbar spine there is no change in the blood pressure; if it reaches the first thoracic the pressure becomes *nil*. If the nerves controlling the diaphragm and intercostal muscles are anaesthetized, respiratory embarrassment arises. If it reaches still higher levels the sympathetic cardiac accelerators are anaesthetized, and unrestricted vagus action slows down the heart. Extreme pallor, nausea, vomiting, a cold clammy sweat, a feeling of pressure over the precardium, thirst, air-hunger, and the fear of impending danger are the alarming symptoms such diffusion of the anaesthetic causes.

With an endeavour to overcome any or all of these objectionable symptoms of an otherwise ideal anaesthetic a series of experiments were conducted to ascertain the physiology and the physiological action of the various drugs advocated for spinal anaesthesia. We attempted to bring the anaesthetic under the control of the operator, to prevent uncertainty as to the parts involved, to stabilize the intensity and regulate the time of anaesthesia, to diminish the tremendous drop in blood pressure, to minimize nausea and vomiting, to abolish cold sweats and

* Read in opening a discussion in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Manchester, 1929.

anxiety of the patient, to eliminate air-hunger and cardiac pains, to solve the mystery of post-anaesthetic headaches, to prevent localized peristalsis and systemic disturbances.

We set out to produce a spinal anaesthetic that would minimize the toxic reactions, be certain in effect, constant in duration, act in direct ratio to the amount of anaesthetic agent injected, would not in any way affect the heart action, vascular tension, or respiratory function; one that would lessen nausea and vomiting, abolish pallor and cold sweats, that would eliminate the anxiety of the patients as well as systemic disturbances and after-effects; one that would restore, if possible, the confidence of the surgeon to this form of anaesthesia. A new anaesthetic compound had to be devised and the technique so modified that the procedure could be carried out almost with the exactness of the micrometer, if the desired results were to be obtained. Some of the experiments and the reasons for our deductions in devising spinocain may be of interest.

To obviate anaesthesia—temporary paralysis of the thoracic voluntary nerves and sympathetic chain—diffusion of the anaesthetic within the subarachnoid space must necessarily be prevented. Our experiments were carried out with tubes shaped to conform to the human spine. In the larger tubes we employed an isotonic solution, in the smaller tubes with a capacity of 40 min. human spinal fluid was used. In these tubes we studied the action of various viscid substances in an endeavour to secure a solution that would mix but not diffuse with spinal fluid, that would remain *en masse* until the anaesthetic drug had become fixed or absorbed. A substance that would not inhibit anaesthesia but regulate its durability and intensify its action had to be found, always bearing in mind the oscillatory action of spinal fluid within the dural sac due to vascular pulsations, and the external physical disturbances, such as are caused by respiration, coughing, motion of the body, straining, vomiting, etc.

To simulate the first, a clock-like arrangement was devised that would pulsate against a rubber cap; to produce the action of the latter disturbances, a bulb arrangement was attached to the tubes as well as an oscillating device. The first would increase or decrease the interspinal pressure in the tubes from 1 to 8 mm. of mercury; the slight oscillation compensated for the motions of the body. To prevent diffusion we employed many viscous agents, some of which had been advocated before. But, by the use of a solution of starch paste, we were enabled to prevent dissemination for forty minutes. This solution, even in sealed ampoules, could only be used when fresh. It would ferment, precipitate, and become unstable within six to eight weeks. Later we discovered that gliadin (the mucilaginous content of wheat starch) was the substance that really produced the viscid properties desired. This is relatively insoluble, being soluble only in certain alcoholic solutions. If the alcoholic content is increased or diminished it will precipitate out of the solution in crystalline masses. From gliadin we were able to produce a jelly-like gelatinous substance that we chose to call amyloprolamin, which was stable, soluble, prevented dissemination for over two hours, or until the anaesthetic drug was spent. This was necessary because we observed that by dissemination any anaesthetic solution became weakened by dilution. This accounted in a great part for the uncertainty of duration and variation of intensity of various methods formerly employed in spinal anaesthesia.

To further check the action of the solution within the subarachnoid space and to determine whether a definite and fixed volume could be maintained throughout the duration of the anaesthesia, to prove that dissemination would not occur in a cephalic direction, we coloured the solution with methylene blue and tapped human spines from twenty minutes to one hour after the original injection. We obtained no coloured solution from the sixth or seventh thoracic interspace. Its action was further checked by adding stains to the solution, injecting it into the dural sac of dogs, and noting the stained regions of the cord and arachnoid in necropsy specimens.

To enable us to control the anaesthetic so as to bathe only the spinal nerves desired, it became necessary to determine the capacity of the dural sac at various heights in adults and children of various ages. This was accomplished by colouring the spinocain with methylene blue and making taps along the spine until we obtained clear fluid. A further check was made by adding eosin to the light and heavy solutions and injecting these into cadavers, the body being maintained in a position similar to that of the patient on the operating table. The solution was found to expand in a like manner. The results were observed by performing a laminectomy. We added sodium iodide to a solution of the same specific gravity and viscosity as spinocain and injected this into the spinal canal of cadavers and radiographed them. The results verified our other findings. With the dural sac capacity determined it was easy to anaesthetize various pairs of spinal nerves at will, by expanding the solutions as has been described in the technique.

The toxicity of novocain injected intradurally is practically the same as when introduced intravenously. When 300 mg. of normal saline were injected into dogs weighing 9 kg. (20 lb.) convulsions occurred, followed by death. If liquid alboline or olive oil was employed as a solvent for the novocain before it was dissolved and injected into the subarachnoid space, satisfactory anaesthesia was obtained. Although it was delayed, the duration was extended, and by elevating the hips of the dog we were enabled to limit anaesthesia to the legs only. Anaesthesia appeared to be more intense, and with the oil preparation convulsions did not occur in the six dogs injected. There were no toxic reactions when as much as 750 mg. of novocain were employed. The viscosity of the amyloprolamin solution acts similarly to the oils, and materially reduces the toxicity of novocain within the subarachnoid space. This is well exemplified by the introduction of a sufficient amount of spinocain to be equivalent to 1,200 mg. of novocain into a patient weighing 135 lb., when no toxic symptoms or vascular relaxation resulted. It prolongs the time of absorption and extends the duration of anaesthesia. When novocain is dissolved in normal saline or spinal fluid, 120 mg. is considered a maximum dose, but with the use of spinocain we do not hesitate to use amounts equivalent to 400 or even 600 mg.

The selection of novocain as the most desirable anaesthetic agent resulted from a study of the physiological action of the drugs ordinarily used in spinal anaesthesia. Stovaine produces the most intense anaesthesia—a complete and absolute transitory paralysis and anaesthesia of not only the sensory nerves, but also the motor nerves, the tactile and thermo sensation, the sphincters and the vasomotors of the anaesthetized field. It may, if not acidified, produce incomplete anaesthesia. The alkalinity of the spinal fluid often causes the stovaine to crystallize out of the solution injected into almost insoluble particles. Traces of stovaine have been found in the spinal fluid twenty-six hours after injection. As the anaesthetic is subsiding it often produces severe pains in the lower limbs; headaches of a hypertonic nature occasionally follow its use. Tropacocaine produces anaesthesia not unlike stovaine, with perhaps a slightly lessened action of the vasomotors. Apothesin gives a perfect anaesthesia and complete relaxation. Tactile sensation is not constantly impaired. Primarily there is very little vasomotor disturbance, its absorbability is slow or retarded. Secondarily, and in one or two hours after injection, it produces a severe vasomotor disturbance. Cases have been observed without more than a ten to fifteen points drop in blood pressure within forty minutes. Two hours after the injection the pressure had dropped to zero in many cases. This secondary action does not occur with any other drug but butyn. At times it is impossible to raise the patient's head for twenty-four hours after administration. Apothesin, stovaine, and butyn have been considered too dangerous to use, and we have abandoned them for this reason. Novocain gives a complete anaesthesia of the sensory nerves, satisfactory relaxation, and affects the tactile and muscular sensation only slightly. It affects the vasomotors less than any other drug used. Thermosensation disappears with all drugs. Occasionally the motor nerves are not involved with novocain, but this is not constant.

It is interesting to note that a 100 per cent. solution of novocain-amyloprolamin solution, used to produce intra-

dural sacral anaesthesia, caused no appreciable increase in the cell count of the spinal fluid. But the acid anaesthetics, as apothesin and stovaine, produce a marked increase in the number of cells, and not infrequently we have observed 15, 20, and as many as 25 cells to the cubic millimetre after a 5 per cent. solution of the latter had been injected. The anaesthetic agents with an acid reaction increase also the intradural pressure.

A transitory or prolonged paralysis of the hind legs was produced in 30 per cent. of our dogs after a 5 per cent. stovaine solution had been introduced into the subarachnoid space. This paralysis lasted from six hours to nine days. All cases in which stovaine was employed showed a perivascular round-cell infiltration, and by the Cajal method of nerve staining we found the axis cylinders swollen, marked degeneration of the fibres of the anterior roots, and in a dog that was paralysed for five days the sciatic nerve showed marked degeneration of the nerve fibres. On the other hand, novocain in 5, 10, and 20 per cent. solutions failed to produce any macroscopic or microscopic changes.

The absorption time of various anaesthetic agents from the spinal fluid shows great variations. Traces of stovaine have been found in the spinal fluid twenty-six hours after introduction; whereas all traces of novocain had disappeared in innumerable cases in four hours, and in all cases in six hours. In mentioning novocain, I include neocaine and procaine, as they are all nearly identical, the only variation being in the manufacture of the product and not in the primary formula.

Deductions led us to believe that novocain is absorbed by the nerve trunks, and enters the system in this way, rather than through the veins or lymphatics by osmosis. As has been shown, the osmotic rate between spinal fluid and the venous blood is very slow, due to the similarity of intravenous and intraspinal pressure. With the patient in a reclining position the former is 3 to 4 mm. Hg, and the latter is 6 to 8 mm. Hg. This may also account for the fact that if a vein is accidentally punctured during a spinal tap, bleeding does not occur into the spinal canal, but there is a possibility of seepage of spinal fluid into the vein. Possibly this accounts for the frequent hypotonic headaches, as these headaches are observed more frequently after blood enters the spinal needle or after bungling attempts at a spinal tap.

Intraspinal pressure with the patient in a sitting posture is greater than when the patient is recumbent, but there is no difference between the pressure of a recumbent patient and one in a 45 degree Trendelenburg position. This may be accounted for by the cerebral congestion produced when the patient is placed in a position of so marked a degree. This fact is observed if the spinal manometer is permitted to remain attached to the needle intact, when the patient is recumbent, and then placed immediately in a 45 degree Trendelenburg position. A slight remission in the pressure is seen, which almost at once assumes its original reading. We have observed that headaches are more likely to occur when the spinal tap is made with the patient sitting, as with this method a greater amount of spinal fluid is permitted to escape. This is also true when large needles of 15 to 17 gauge are employed. They permit seepage through the dura into the surrounding tissues, and not infrequently cause post-operative backaches, either as a result of the oedema by the spinal fluid or trauma of the tissues. A long tapering point is likely to produce more bleeding than the short bevelled fine-gauge needle.

We conducted a series of tests and animal experiments with all the drugs that have been advocated as vaso-constrictors. Strychnine, intradurally, was the only one that showed satisfactory results in the presence of novocain. These tests and animal experiments were not only in relation to intradural circulation, but the drugs were introduced intravenously, intramuscularly, and subcutaneously. Of the so-called stimulants, strychnine is the only one with any definite value, with the exception of ephedrine and suprarenin. Ephedrine and suprarenin combined, and introduced intravenously, proved the most effective as well as lasting. Suprarenin has little or no value when injected into the muscles, where it produces a localized ischaemia which delays absorption. These experiments enabled us to establish a ratio of the approximate amount of ephedrine required for the stabilization of definite amounts of novocain, with anaesthesia at various heights on the body surface. We also learned how much of ephedrine-suprarenin mixture should be used to cause a hypotension case to approach normal and maintain a constant pressure for from four to six hours, as well as how to gauge the dosage of ephedrine in hypertension cases. Given a case of hypotension of 67/42, 50 mg. of ephedrine and 0.7 mg. of suprarenin introduced intravenously will increase the pressure to approximately 120/70, which will be maintained for at least four hours from the time of injection, during which time one can proceed as with a normal case. A hypertension case of 200/110 pressure, however, should not have over one-half the amount of ephedrine that would ordinarily be used in a case with a pressure of 120/70, or 25 mg. of ephedrine.

Bearing in mind that the vaso-constrictors leave the cord by way of the anterior nerve routes from the second dorsal to the third lumbar vertebra, one must estimate the amount of ephedrine necessary to maintain a constant pressure. With intradural sacral anaesthesia none is required. When the lumbar nerves are bathed in spinocain, with anaesthesia of the legs, 25 mg. should be used. If the anaesthetic is to be carried to the ninth dorsal for anaesthesia up to the umbilicus, 50 mg. should be employed. If the anaesthesia is to expand to the sixth dorsal and anaesthesia to the uniform process, 60 to 100 mg. of ephedrine will be necessary. Strychnine intradurally stimulates the vaso-motor constrictors, but will have little or no effect if injected intravenously or intramuscularly. Ephedrine will fortify the anaesthetized nerves, stimulate the unaffected vaso-constrictors, and if administered before the spinocain will stabilize the arterial pressure. Ephedrine should fortify the vasomotors against the attack of the anaesthetic. To obtain the best results it must be injected before the spinal tap is made. The result will be disappointing if used after the pressure has fallen, and the vaso-constrictors have become anaesthetized, as it will not re-establish a normal pressure if employed at this time. We should then resort to an intravenous injection of 50 to 60 mg. of ephedrine and 0.7 mg. of suprarenin combined.

There has been considerable discussion as to the toxicity of ephedrine. Two of my colleagues have reported deaths which they attributed to the administration of 50 mg. doses. There must have been some error in their conclusions. With an effort to estimate the maximum safe dose we used a 1 in 1,000 solution in rats weighing 100 grams, and by transposing our findings in ratio to a human being weighing 72 kilograms (160 lb.) the lethal dose was estimated at 13,200 c.cm., or 13 grams. The maximum safe dose, according to Solis-Cohen and Gilhens, is 5 grams.

As a result of these studies and reports on 1,100 primary inductions (the total is now 160,000) with controllable spinal anaesthesia—performed by surgeons in every State in the Union and several foreign countries—we feel justified in asserting that spinocain is controllable within the dural sac. The physiological action of spinocain is quite different from that of any other spinal anaesthetic, inasmuch as nearly all of the objectionable features of the others are eliminated. When local conduction or spinal anaesthesia is used, the paramount issue at all times is never to hurt the patient in any way. The patient once hurt may lose confidence in the method and in the operator. A lost confidence may be very hard to regain, and frequently constitutes the direct cause of unsuccessful anaesthesia. A patient who is immediately subjected to one painful manipulation becomes hypersensitive to every following procedure. In spinal anaesthesia with novocain it must be remembered that tactile sensation is not abolished. All the more reason why every precaution should be taken, and the technique employed with such finesse that spinal anaesthesia may be administered without producing any pain. With an entirely satisfactory anaesthesia the patient should be cheerful and comfortable throughout the operative procedures.

To enable us to carry out this technique with as few manipulations as possible, and to place at our disposal solutions that could be controlled within the subarachnoid space, we devised the ephedrine-novocain solution, and

the light and heavy spinocain. The ephedrine-novocain ampoule consists of ephedrine 50 mg. and novocain 10 mg. The light solution of spinocain has a specific gravity of 1.0005. It contains: strychnine 2 mg., novocain 200 mg., amyloprolamin 130 mg., ethyl hydrate 300 mg., normal saline q.s. 2 c.cm. The heavy solution has a specific gravity of 1.109, and contains: strychnine sulphate 2 mg., novocain 200 mg., amyloprolamin 130 mg., propantriol 100 mg., and normal saline q.s. 0.5 c.cm.

The heavy solution should always be given with the patient sitting or in a marked Fowler's position. After administration patients should never be placed in a Trendelenburg position; they should, if possible, be maintained in Fowler's position for at least two hours. If for any reason it becomes necessary they may be placed flat for from fifteen to twenty minutes after the anaesthetic has become fixed.

It would hardly seem necessary to repeat the details of technique for the use of spinocain anaesthesia, as that was described in the October issue of the *British Journal of Anaesthesia*. The method of using the heavy solution is again explained by the author in the current July issue; also in an article by Dr. Frank A. Kelly. There are, however, a few points that should be emphasized as essential to the perfection of this form of anaesthesia. The needles used should be of small calibre, 22 gauge, with a short tapered point, and made of a special alloy of chrome steel that will neither rust, corrode, nor break on bending. To reassure oneself that they are safe for use they should be bent into a semicircle, with the stylet removed, before sterilization. The point of the needle should at all times be very sharp: in fact, it is a good practice never to use a needle twice without resharpening. There is a certain sense of "touch" that one acquires which materially facilitates a lumbar puncture. The development of this is essential to obtain the best results. A large needle will traumatize the tissues, permit seepage of the spinal fluid, produce an increased cell count, and cause post-anaesthetic headaches, to say nothing of the injury to the strands of the cauda. A long tapered pointed needle causes bleeding more frequently at the time of puncture, and it is often the direct cause of unsatisfactory anaesthesias. Owing to the fact that a part of the taper is within the dura and the remainder outside when the solution is injected, a portion escapes extradurally. A part of the long tapered needle may be within a vein, and when concentrated solution is introduced intravenously novocain convulsions may result. An all-steel needle is very apt to break within the tissues if the patient moves or jumps, or if side pressure is applied. The extraction of a needle from the interspinous ligament is not a pleasant experience.

The syringes should be light, and preferably of the all-glass type. It is advisable to fit the needles to the syringe before they are sterilized, to reassure oneself that there is no leakage between needle and syringe, or against the possibility of aspirating air into the syringe. They should be so constructed that the piston works freely in the barrel; there should be no leakage about, or sticking of the plunger. It is advisable, but not essential, that the syringe should have a suitable locking device that will not permit the needle to become detached when in use.

When the anaesthetic is to be injected with the patient in a prone position the posture must be essentially correct—that is, lying on the side with the knees flexed upon the abdomen and the head bent forward, the chin resting on the chest, the back bowed outward. The hips and shoulders should be in the same plane. If the shoulders are tilted and the hips vertical, or the hips tilted and the shoulders vertical, "a corkscrew spine" results. With this condition dry taps may be produced, bleeding may be caused, or the needle may deviate to the side of the dura, and unsatisfactory results will be obtained. The size of the subarachnoid space varies in different individuals, but with a little experience one will quickly learn the extent of expansion of spinocain necessary to produce anaesthesia on the body surface at various heights. Better results will be obtained if the patient is allowed to remain flat on the table for three to five minutes after injection, or until such time as anaesthesia has reached the desired height. Then the degree of Trendelenburg position is assumed as measured by the tiltometer.

Children tolerate spinocain anaesthesia very well; in fact, they are able to withstand larger doses in proportion to the body weight than the adult. It must be remembered that the cord extends lower in infants and children than in the adult. Therefore it is necessary to make the spinal puncture in the fourth interspace so as to avoid accidentally injuring the cord. To determine the amount of spinocain one should consider the body weight of the infant rather than the age. The spinous processes are not fully developed, and this lessens the distance from the skin to the dura. The accompanying table shows the age, weight, distance from skin to dura, amount of spinocain advocated, the mechanical expansion required, and the approximate duration of anaesthesia. I am offering this as an aid to those who may be unfamiliar with the technique in children.

Age.	Weight.		Height.		Distance from skin to Dura.		Amount of Spinocain.		Mechanically to expand to	Duration of Anaesthesia (minutes).

For intradural sacral anaesthesia, with the light solution, a 15 degree Trendelenburg position should be assumed at once. With the heavy solution the patient should remain sitting after injection until the anaesthesia has become fixed; he should then be placed in a reverse Trendelenburg position. *One should not confuse the light and heavy solutions;* if this happens, a case of collapse may occur, due to the ascent of the solution in a cephalic direction.

Morphine and scopolamine are necessary, not to intensify the anaesthesia, but to allay the fear and apprehension of the patient. For upper abdominal work the first lumbar interspace should be selected. With the patient in the prone position the second interspace is usually the wider and more accessible; it is the interspace of choice. In children the level of the conus medullaris should always be borne in mind. In infants it terminates at the fourth lumbar; in children from 4 to 5 years of age it is found between the second and third; from 10 to 11 years at the second lumbar. It does not ascend to the dorso-lumbar interspace until early in adult life. The site of puncture should be selected accordingly.

For prolonged operations 2, 3, or 4 c.cm. of spinocain may be used with safety, provided an equalizing amount of ephedrine is employed. For nervous individuals it is always advisable to use 0.5 to 1 c.cm. more than in a normal case.

as this produces a deeper and more intense anaesthesia, that will greatly diminish tactile sensations, which often disturb the hypersensitive patient. One should never attempt to introduce spinocain except into the lumbar spine, never above the conus medullaris. The introduction of a local anaesthetic directly into the cord substance may, and probably will, result in an instantaneous catastrophe.

Spinal anaesthesia is adaptable in all classes of cases, be the blood pressure high or low, the patient young or old, fat or thin, cardiac, diabetic, alcoholic, or addict. Should the blood pressure be extremely low it may be elevated to normal by the intravenous injection of suprarenin and ephedrine combined. Our youngest patient was 2 months and the oldest 91 years of age.

Patients suffering from tuberculosis, bronchitis, asthma, renal toxaemias, pyelitis, diabetes, or arterio-sclerosis should not be subjected to the harmful influences of inhalation anaesthesia.

In the acute abdomen this form of anaesthesia almost becomes a matter of life or death: morbidity is lessened, convalescence shortened, and the mortality rate lowered.

Spinocain offers more protection to the patient and better working facilities to the surgeon. It has been taken up as a routine anaesthetic by innumerable American operators, because they realize the above conditions. The revived enthusiasm of spinal anaesthesia in America can hardly be estimated. An idea of the recent increase in spinocain anaesthesia may be obtained by attending any of the National Surgical Association meetings. It is the safest form of anaesthesia we possess for operative procedures below the costal margin.

Concluding, I do not wish to advocate the use only of spinal, conduction, or local anaesthesia, but I wish to emphasize that past experiences have taught me that with their use we can prevent the aftermath of operations—the nausea, vomiting, distension, ileus, acidosis, pneumonia, and innumerable other complications—which are directly or indirectly attributable to inhalation anaesthesia. Patients no longer fear an operation or dread the effects of the anaesthetic. Permit me to foretell that within ten years, possibly less, local, conduction, or spinal anaesthesia will be the anaesthetic procedure of choice.

THE CLINICAL ASPECTS OF CONTROLLABLE SPINAL ANAESTHESIA.*

BY

FRANK A. KELLY, M.D.,

DETROIT, U.S.A.

IT has been said, and we thoroughly agree with the statement, that "all textbooks on spinal anaesthesia will have to be rewritten as a result of the epochal work of Dr. George Pitkin." My object in writing this article is twofold: first, to try and shed some light on the subject; and, secondly, to correct some of the erroneous impressions that are abroad concerning it.

This subject is a very old one, dating back to the work of Corning in 1888, and during the forty years there have been many successes and failures, many advocates and detractors. In some localities and with some operators it has gradually gained and held favour, but in most cases it has been doomed to early failure and disuse. In the last few months, however, it has received a tremendous impetus, as note the great number of articles published in the last year; particularly I would call attention to the December number of the *American Journal of Surgery*, where no fewer than fourteen different articles appear on the subject. I believe this great impetus is largely due to the admirable work of Dr. Pitkin and his associates of Teaneck, New Jersey, and his development of a new solution. Dr. Pitkin has used every effort to have this method thoroughly tried out, and has worked out a technique which to my mind does away with the objections to the older methods of spinal anaesthesia.

The main objections in the past have been, first, the transitory nature of the anaesthesia; secondly, lack of control of the height or extent of the anaesthesia; thirdly, the serious depression of the blood pressure. The technique devised and first advocated by Dr. Pitkin, and now by a host of his followers, completely negatives all of the above objections, and with them other objections that one so often hears.

First, the transitory nature of the anaesthesia is corrected by making the solution viscid by the addition of gliadin (the active principle of wheat starch). This very greatly prolongs the period of the anaesthesia—our usual anaesthesia now lasting from one and a half hours to two hours.

Secondly, the height or extent of the anaesthesia is controlled by the tilting of the table and expansion of the solution. Owing to the fact that the anaesthetizing agent is lighter than the spinal fluid and floats upon it, the upper extent of the anaesthesia is very definitely controlled by placing the patient in the Trendelenburg position as soon as the anaesthesia has reached the desired height.

Thirdly, the severe drop in the blood pressure is controlled by ephedrine, used before the spinal injection in an amount to be determined by the existing blood pressure, and is repeated or added to as the case requires, always keeping the blood pressure within the range of normal. One must bear in mind, however, that the ephedrine will not act as efficiently after the spinal anaesthesia has been administered as before.

Formerly the systolic blood pressure of less than 100 mm. of mercury was considered a contraindication to spinal anaesthesia. Now, having a patient with a low systolic pressure, ephedrine is used in sufficient quantities to raise the blood pressure to the desired amount and the operation is started. Frequent blood pressure readings are taken and the blood pressure is maintained by the use of further ephedrine, if needed; 1/30 grain of strychnine is also added to spinocain, or spinal anaesthetizing agent, as it has been shown that this has a decided effect on the vasomotor nerves if given intraspinally.

To act intelligently one must thoroughly understand the cause of the drop in the blood pressure. It must be remembered that *all* the vasomotor nerves controlling the blood vessels of the body are given off the spinal cord from the second dorsal to the third lumbar segment. Therefore, if the anaesthetizing agent is allowed to extend as high as the second dorsal all the vasomotors will be paralysed and a very considerable blood pressure drop will take place. This illustrates the very great value of the controllable feature of this anaesthetizing agent, because it can be limited to lower levels so that a large portion of the vasomotor nerves are not affected.

Another safety factor is of the greatest importance in the use of this lighter specific gravity solution: if a blood pressure drop of serious proportions should occur, and even if the ephedrine should not control it (a circumstance we have never encountered), the head of the table, which is already lowered, should be lowered still more, and this in itself would cause blood to flow to the brain by gravity and prevent a cerebral anaemia, even if all other methods fail. It is a well-understood fact that the blood pressure drop is due to the involvement of the vasomotor nerves, with the consequent "pooling" of most of the blood in the splanchnics. The method of putting the patient into a decided Trendelenburg position always causes a flow of pooled blood to the brain, even if there is no recordable blood pressure. I think we will all agree that gravity will not fail us even though all other methods may, and we will continue to have a sufficient amount of blood in the brain to carry on the necessary functions of life. The importance of this is at once recognized by the fact that our great interest in blood pressure depression is really one of fear of serious cerebral anaemia.

The use of ephedrine before the spinal injection is made is essential for two reasons: first, that ephedrine will act much better before anaesthesia; and secondly, that we believe in the *prevention* of a serious blood pressure

* Read in a discussion in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Manchester, 1929.

depression rather than in attempting to correct it after it has happened.

It is of great importance in this type of anaesthesia that we know the absolute degree of the tilting of the table and the tilting to be used in the control of the extent of the anaesthesia. For this purpose we make use of the tiltometer devised by Dr. Pitkin.

It will be well at this time to explain the extent of the high and low anaesthesia and the technique by which they are obtained, bearing in mind that we never operate under spinal anaesthesia above the costal arch.

The extent of the low anaesthesia is that of a true sacral or caudal anaesthesia secured by an intradural injection. The technique for securing this anaesthesia—where only the perineum, vagina, and rectum are involved, taking in the urethra but not the fundus of the bladder, also the cervix of the uterus but not the fundus, together with the so-called saddle anaesthesia down the inside of the thigh for a short distance—is obtained by injection of one-half an ampoule of spinocain into the fourth lumbar interspace without any mixture with the spinal fluid and having the patient immediately tipped into at least a 15 degree Trendelenburg position. This anaesthesia is ideal for operations on the vagina and rectum. It does not anaesthetize the legs or abdomen. It is especially well adapted to obstetrics, except for one thing, and that is that the patient has to be put into the Trendelenburg position, and thus would have to propel the foetus in an upward direction. We therefore find that the heavy solution, while the patient is in the reversed Trendelenburg position, or Fowler's position, is better adapted to confinement work. Here also a true caudal or sacral anaesthesia can be secured by the subarachnoid injection.

The extent of the high anaesthesia that we use is the anaesthesia to the costal arch for such operations as those on the gall-bladder, etc. This anaesthesia is accomplished by making the injection in about the first lumbar interspace and mixing with the anaesthetizing agent about 6 c.cm. of spinal fluid. This so expands the anaesthetizing agent that it will give anaesthesia to well above the costal arch, and when this anaesthesia is complete to the desired height the patient is immediately placed in the Trendelenburg position and the upward movement of the anaesthesia is at once stopped.

The various degrees of anaesthesia between the extent of the high and low anaesthesia already referred to are accomplished by a modification of the two above-mentioned methods.

Many contraindications to spinal anaesthesia have been mentioned in the literature, but we find that there are no contraindications to its use except a persistent thymus and a patient who is in an absolutely moribund state. Both extremes of age tolerate spinal anaesthesia very well. Many patients as young as 2 or 3 weeks, and others over 80 years of age, have been operated upon under this method.

Rarely a patient feels nauseated during the operation, and there will be some drop in the blood pressure. The transitory blood pressure drop due to nausea should be disregarded, as it will immediately come back after the nausea feeling has passed off, which always occurs in a very short time. The blood pressure drop otherwise is always in relation to the number of vasomotor nerves involved, and hence in relation to the height and extent of the anaesthesia.

An objection to spinal anaesthesia which is frequently heard is that of post-operative headaches. In our series of cases we have had several patients who had a slight headache and two patients who had a severe headache. These severe headaches were very quickly and permanently relieved by a retention enema of 6 ounces of a 50 per cent. magnesium sulphate solution.

It is generally conceded now that many of the severe headaches in the past were due to the choice of a spinal needle with a long point, either one that was too large or one with a long sharp point. Dr. Pitkin has devised a needle with a very short bevel which is sharp only on the very point, the rest of the bevel being rounded so that it does not cut a section out of the dura, but really makes a miniature trapdoor in the dura, which immediately closes with the withdrawal of the needle, and does not allow leakage of the spinal fluid afterwards.

Many writers on spinal anaesthesia in the past, and in fact some of them in the present, speak of a very decided lack of bleeding in the wounds. It must be apparent to anyone who gives the matter thought that these so-called "dry wounds" can be the result of only one condition, and that is an extremely low blood pressure. We have not found this condition in any of our cases, and should be very much surprised and alarmed if such a condition should arise.

It has been our experience in doing very high abdominal surgery, such as extensive gall-bladder and common duct surgery, that if the anaesthesia was carried to a high enough level to allow us to complete a long operation without difficulty, some of the patients have complained of a feeling of weakness and difficulty in breathing. We attribute this to the fact that a number of the intercostal nerves have been involved. It has therefore been our practice to limit the height of the anaesthesia a little more closely in this work, supplementing it with an intercostal block of the eighth, ninth, tenth, and eleventh costal nerves at the angle. This has made it unnecessary to have the anaesthesia quite as high as otherwise would be needed. Since we have employed it we have had no difficulty due to respiratory embarrassment.

A word of explanation should be made in regard to the relative action of ephedrine and adrenaline. The action of adrenaline is more transitory, but more quickly available if given intravenously, than that of ephedrine; however, ephedrine will act just as quickly as adrenaline when given subcutaneously or intramuscularly, owing to the fact that adrenaline causes an ischaemia which holds it in this location, and this ischaemia is not caused by ephedrine.

In testing for the height of anaesthesia one should carefully distinguish between pain sense and tactile sense, as it is very apparent that tactile sense remains considerably longer than pain sense in the anaesthetized area. This is also true of thermal sense.

Everyone who has seen operations performed under spinal anaesthesia very quickly notices the presence of an active peristalsis. A very definite reason for this exists, the explanation of which is as follows: the vasomotor nerves (the source of intestinal inhibition) are blocked, and the sympathetic automatic influences from the vagi and the motor stimulus from the ganglia of Auerbach are left unopposed. The increased peristalsis, you will readily see, is of tremendous value, particularly in cases that are very toxic and are to a certain degree dehydrated or have paralytic or adynamic ileus. It is also especially valuable in the toxic cases because of the fact that the toxic matter in the intestines is so much more readily evacuated. It must be remembered in this connexion that ether often stops all peristalsis for many hours after its administration. Spinal anaesthesia produces true anoci-association, as all the nerves in the affected area are completely blocked.

Experimental study shows that barbital is a very definite antidote to novocain poisoning, and while the very small amount of novocain that is used in these cases will hardly ever need any antidote, we always aim to be on the safe side, and our routine orders are to give 10 grains of barbital one hour before the operation. The experiments of Dr. E. G. Martin and his associates of Detroit would tend to prove that 340 grains of novocain could be given to an individual weighing 170 pounds, and his life be saved by the administration of 120 grains of barbital. It is our practice always to have an ampoule of soluble barbital in the operating room, but thus far we have never had occasion to use it.

I would particularly recommend in speaking to the laity that the word "spinal" be not used, and would suggest in its stead either "lumbar" anaesthesia or "local" anaesthesia, as it has been our experience that many people have a dread of anything entering their spinal canal, as it is in their mind in some way associated with their brain.

Dr. Wayne Babcock of Philadelphia says of spinal anaesthesia: "It is a very personal method strongly appealing to the temperament of certain operators but equally unadapted to others."

NINETY-SEVENTH ANNUAL MEETING
OF THE

British Medical Association.

Held at Manchester, July, 1929.

THE SECTIONS.

SUMMARY OF PROCEEDINGS.

FULL reports of the opening papers communicated to the Scientific Sections of the Annual Meeting at Manchester will be published in the *British Medical Journal* during the next few months. The summaries of discussions printed below, and those which will appear in subsequent issues, are intended to give members who were not present a general idea of the proceedings.

SECTION OF MEDICINE.

Wednesday, July 24th.

CARDIO-VASCULAR SYPHILIS.

THE PRESIDENT opened the proceedings by outlining the programme of work lying before the members attending its meetings. He was followed by Dr. J. M. COWAN (Glasgow), who, in an excellent paper, initiated a discussion on cardio-vascular syphilis. In this he dealt with the incidence, etiology, and pathology of the condition, adding valuable remarks on its treatment, and illustrating the subject with photomicrographic slides and tables of statistics. He was followed by Dr. BOYD CAMPBELL (Belfast), who discussed the effect of treatment on the Wassermann reaction of these patients, dwelling on the importance of giving mercury and potassium iodide in addition to the customary arsenical preparations. Prolonged and repeated courses of treatment were recommended, and the apparently harmful influence of intercurrent secondary infections on the Wassermann titre was illustrated. Dr. CRIGHTON BRAMWELL (Manchester), who confined himself to a discussion of the clinical symptoms displayed in cardio-vascular syphilis, endeavoured to correlate such arrhythmias as extra-systoles, paroxysmal tachycardia, and heart-block with the existence of a syphilitic infection, which he stated was but rarely the cause of auricular fibrillation. Professor A. S. WARTHIN (Michigan) gave a full account of the macroscopic and microscopic appearances of cardiac syphilis, illustrated by a number of lantern slides from specimens admirably prepared and stained. He had found that some of the so-called myxomas of the heart were syphilitic in origin, and crammed with spirochaetes, and might well be called myxogummas; it was interesting to note that an English observer had applied this term to these tumours a hundred years ago. Professor WARTHIN showed a number of slides illustrating the myocarditis of congenital syphilis, and dwelt on the difficulty met with by clinicians in distinguishing such cases from cases of rheumatic infection. He referred to the very high percentage of the hospital population—about 60 per cent.—that gave microscopical evidence of syphilitic infection, and remarked on the fact that the lesions characteristic of syphilitic myocarditis, so common in the male, were quite rare in the female heart, a fact attributable to some radical constitutional difference between the two sexes. Sir HUMPHRY ROLLESTON referred to the absence of any secondary cutaneous manifestations in the patients with these extensive secondary cardiac syphilitic lesions, and questioned the completeness of the so-called cures of syphilis effected by the arsenical drugs. Dr. STARLING (Norwich) contrasted the difficulty of securing complete data in private practice with the comparative ease with which they can be obtained from patients seen and treated in well-equipped hospitals, and gave an account of his own methods of treatment in cases of cardio-vascular syphilis. Dr. SPEARES (Dublin) emphasized the importance of a good skiagraphic examination in the diagnosis of aneurysm of the aorta, quoting a number of cases in which all the commoner physical signs relied on in its diagnosis were absent, though the skiagram gave positive evidence; in others, again, weakness or paralysis of one vocal cord might be the only positive evidence. He was followed by Dr. ILLINGWORTH (Preston), who spoke on treatment; and by Dr. NABARRO, who referred more particularly to the case with which congenital syphilis might be overlooked in a child apparently suffering from a rheumatic infection, and to the fact that chorea might be evidence of congenital syphilis. Dr. LANGLEY (Manchester) commented on the relatively low percentage of positive Wassermann reactions recorded by previous speakers; in his own experience a positive reaction was practically universal. Professor HAY (Manchester) discussed the effect on treatment of finding a positive reaction, and pointed out the difficulties that might be created by such a discovery if, as had been suggested by one speaker, the antisyphilitic treatment should be prolonged for the duration of life, and, as had been suggested by another, syphilis might properly be regarded as incurable by treatment. He asked if it was not the case that many patients with cardio-vascular syphilis were best served by treatment for cardiac failure only. This question was later considered by Dr. CAMPBELL, who quoted instances in which antisyphilitic treatment proved of great benefit after treatment for cardiac failure had proved comparatively unsuccessful. Dr. COWAN briefly replied to a number of questions that had been raised during the discussion; and Professor WARTHIN, in reply to questions asked by various speakers, observed that in his experience aortic aneurysm was practically always due either to syphilis or a streptococcal infection, and that in the former both the Wassermann and the Conn tests frequently gave negative results, though the microscopical examination might show later on that the aortic tissue was packed with spirochaetes. He commented on the fact that the ovary was apparently highly immune to syphilis, while the testis was particularly prone to be attacked by it. He added that he had not yet met with a true case of a second infection with syphilis in a patient supposedly cured of a first attack; should such cases actually occur, the explanation might perhaps lie in a superinfection with a second strain of spirochaete differing from that which had produced the first infection. The PRESIDENT (Professor G. R. Murray) thanked Professor Warthin for the excellence of his address and of his lantern slides.

Dr. PARKES WEBER read a paper entitled "Endocrine tumours." He pointed out that the cells of certain malignant new growths endeavoured to carry on the secretory functions of the particular glandular tissue from which they originated, and discussed the possible action of such secretions on the tissue of the rest of the body. From this point of view the removal of endocrine tumours by the surgeon might actually be harmful to the body as a whole.

SECTION OF SURGERY.

Wednesday, July 24th.

DIVERTICULITIS.

AT the opening meeting of the Section of Surgery, Dr. EDMUND SPRIGGS introduced a discussion on diverticulitis. He said that from combined clinical and *x*-ray examination of the bowel three main stages in the progress of the disease had been discovered:

1. Prediverticular state
2. Stage of formed diverticula } Diverticulosis.
3. Diverticulitis.

Each of these stages had been observed passing into the next, and they were sometimes all present together. As a rule there were no symptoms during the prediverticular stage, but if the lesion was of wide extent pain or burning discomfort was felt. The speaker said that there was pathological as well as radiological evidence of this early prediverticular state. The formation of pouches, according to Keith and also from independent observation, was probably due to irregular sustained muscle contraction analogous to auricular fibrillation in heart muscle. The second stage of diverticula had been found in 10 per cent. of *x*-ray examinations of the alimentary tract. The number and size of these pouches could be well seen in photographs taken after evacuation of the barium meal. Large pouches with wide necks, though they looked the worst, were less troublesome than small narrow-necked diverticula, which produced crescentic and wine-glass shadows. Retention of faecal matter in these was the frequent starting-place of diverticulitis. The wall of the pouches consisted of submucosa and mucosa, but in many there was also muscle. The diverticula might be simple pulsion pouches, but from observation through the stages of development inflammation was a factor. Associated infective foci, especially teeth and spondylitis, were often present. Referring to the etiology, Dr. Spriggs stated that constipation had not been found to be a definite cause, and it was probable that aperients were just as likely a cause, due to chemical and bacterial damage of fluid faeces in the sigmoid. The symptoms and clinical features of the disease were fully surveyed; symptoms occurred most frequently in the first and last stages of the disease. Radiological appearances were definite and diagnostic. Barium shadows in diverticula were not characteristic features. The typical appearances were: (1) inopaque intrusions into the lumen of the bowel, due to inflamed mucosal folds; (2) spike projections of barium from the lumen, due to deformed and contracted haustra and fixity of the bowel, as shown by serial films. It had been found that with an exacerbation of symptoms there was a new attack of diverticulosis. Threatened obstruction occurred in diverticulitis as the result of two conditions: (1) inflamed mucosal folds, and (2) fibrous stricture. It was important to distinguish between these two causes, since douching and warm oil enemas would reduce the swelling in the former and give relief. With the latter condition the risk of obstruction was greater, though in this form douching might give relief. In all the early and many of the advanced cases the disease could be arrested and controlled by medical means. In advanced cases with localized stricture formation there was prospect of complete relief by resection; in other cases, if colostomy had to be performed, it was sometimes possible to restore the bowel by closure of the colostomy at a later date. The treatment of early diverticulitis was the same as that for diverticulosis: removal of septic foci and the institution of a simple and regular diet with a good deal of fruit and vegetables (if possible). The avoidance of aperients was of great importance. Colonic lavage and warm oil enemas at night were of great assistance. Saline douching, though more liable to produce discomfort, had been proved to be more effective in washing out the diverticula than oil enemas. The result of medical treatment in the pre-diverticular state and diverticulosis was very good. The symptoms of subacute diverticulitis subsided rapidly under medical treatment, and the bowel was made more flexible, as detected by both palpation and radiology. Surgical intervention was necessary for perforation, severe obstruction, abscess, and fistula formation, but these complications would become very infrequent as the disease became more widely known and treated. Medical treatment should be employed in all early cases, and resection should never be carried out until the effect of medical treatment had been estimated clinically and radiologically. A portion of bowel with diverticulosis should never be removed on the ground that it might become the seat of inflammation. The situation and localization of the disease was of great importance when considering surgical intervention. Excellent radiograms were shown by Dr. Spriggs to illustrate the various stages of the disease. The development of inflammation at the neck of the pouch was particularly well demonstrated.

Dr. WILLIAM J. MAYO (Rochester, U.S.A.) said that there were two types of diverticula of the colon—acquired and true. The acquired type was concerned in diverticulosis, and was produced by pouches of mucous membrane passing through weak points in the bowel wall. In the true diverticula of the congenital, traction, or pulsion types, all the intestinal coats covered the sac. The diagnosis of diverticulosis was now firmly established on radiological evidence. Some interesting statistics from the Mayo Clinic were given by the speaker, who said that the disease was commoner in men than in women. He agreed with Dr. Spriggs that constipation was not an important etiological factor. Obesity was not always associated with the disease, since it had been found that half the cases were under weight. Cases of diverticulitis could be classified clinically into four types:

1. Self-limiting diverticulitis.
2. Associated with abscess and fistula formation.
3. Associated with obstruction.
4. Associated with carcinoma.

The slow progress and prolonged history of carcinoma of the colon had been demonstrated by review of the earlier histories and examination of the bowel after resection in several instances as being due to diverticulitis, carcinoma being a more recent development. Carcinoma of the sigmoid was nearly twice as common as diverticulitis. Radiology usually distinguished between carcinoma and diverticulitis, and would also usually show carcinomatous change in a diverticulous bowel, but if diverticulitis was present, this diagnostic agent could not be used as freely during the acute stages of the process. Concerning the surgical treatment of diverticulitis, Mr. Mayo said that if the infection went on to pus formation the abscess should be evacuated. In acute obstruction, colostomy should be performed as close as possible to the obstruction, so that at a subsequent operation the diseased bowel and the colostomy could be excised simultaneously through the same incision. In some cases the colostomy could be closed at a later date, after the lumen of the bowel had been restored and the inflammation had subsided. The speaker referred to the serious problems of internal fistula. An important point in technique had been described by C. H. Mayo; after separating and repairing the involved structures, the sutured colon was brought through a hole in the great omentum and attached to the peritoneum of the parietal incision; the omentum was thus thrown between the defects in the colon, bladder, and adherent intestine. In view of the recent investigations of Alvarez on the influence of food products on mass, it would be interesting to compare the incidence of the disease in rice- and fish-eating peoples on the one hand and potato- and red-meat-eating peoples on the other. Some of the phases in the development of diverticula might possibly be due to the sympathetic nervous system. X-ray pictures suggestive of diverticulosis had been obtained by Learmonth and Markowitz after section of the inhibitory nerves to the colon.

Dr. MAXWELL TELLING (Leeds) briefly summarized the advancement in the knowledge of the disease since his paper in 1908. He said that the following points had been learnt: (1) confirmation of the fact that the disease was common and of great importance; (2) perfection of radiological technique and the accurate diagnosis possible; (3) the separation and study of the prediverticular state; (4) the realization that the treatment was medical, surgery being reserved for catastrophes and urgent conditions; (5) the prognosis was not entirely gloomy; (6) the significance and use of the term diverticulosis. He was not convinced about the inflammatory prediverticular stage, and was of the opinion that the main etiological factor was a congenital predisposition to herniation. He had failed to find any evidence of inflammation in the earliest stages of diverticula. Lumbago and fibrositic conditions were the result of toxic absorption; the sigmoid should never be overlooked, in cases of myalgia and arthropathy, as a source of toxic absorption associated with diverticulosis. Dr. Maxwell Telling described, from personal experience, in great detail the symptoms of the disease. As the result of his experience, both in his own case and in his patients, he said that there were certain essentials in treatment—

namely, softening of the faeces by means of liquid paraffin, weekly lavage of the bowel, satisfactorily accomplished by a mild saline purge followed by liquid paraffin, and an ordinary diet with few restrictions. Food leaving solid and indigestible particles, such as nuts, should be avoided, and also abdominal exertion, exercises, or massage. Perforation had occurred in patients while straining at stool. The speaker added that surgical treatment should be postponed until it became inevitable. The use of *B. acidophilus* might be useful in certain cases, but he felt that what was urgently needed for the treatment of this condition was a harmless antiseptic incorporated with paraffin.

Mr. J. P. LOCKHART-MUMMERY said that the radiological evidence of the prediverticular stage described by Dr. Spriggs was unconvincing. Robert Mailer had failed to demonstrate pathologically any such condition. Though there were comparatively few opportunities of direct observation of the colon during the earliest stages, he had been fortunate in seeing the early stage at operation. Small millet seed projections (minute diverticula) were present at points where the blood vessels and lymphatics perforated the muscle coat of the bowel. Inflammation was not present as a rule, but in one case he had noticed inflammation, especially around these small diverticula. This was the earliest stage of diverticulitis. Diverticula were true pulsion herniae of mucous membrane through the muscle coat, and retention of faecal matter in them produced inflammation, which spread into neighbouring tissues. It was probable that there was some degeneration of the bowel wall due to age and unnatural bowel functions. The disease was certainly confined to the later half of life, and occurred most frequently in fat people. There were two definite types of the disease: (1) Inflammation of the colon at an early stage, resulting in an ultimate hard fibrous stricture. This was the type in which obstruction occurred. (2) Diverticula without inflammation — diverticulosis. *Inflammation might occur, as described, giving rise to* abscess formation, peritonitis, and obstruction due to adhesions. A curious unexplained fact was that diverticulitis was most common amongst well-to-do patients. Mr. Lockhart-Mummery added that diverticulitis could be diagnosed with considerable accuracy from the clinical picture. X-ray examination revealed diverticula when little inflammation was present, but in the stenosing type only a filling defect might be seen which was mistaken for carcinoma. Symptoms differed in men and women; in the former, adhesions formed to the bladder, and in the latter, the Fallopian tube, ovary, and uterus were involved. Perforation into the bladder should be prevented. There were often premonitory symptoms of bladder involvement which made early operation imperative. X-ray examination assisted the surgeon in estimating the extent of bowel involved and the degree of stricture. Diverticulitis was a disease with very serious results, and unless the surgeon was called in before complications had occurred, he could often only perform colostomy, which might be permanent. He agreed that diverticulosis and the earlier cases of diverticulitis could be treated medically, but once inflammation was well established it was progressive, and though the condition could be kept in abeyance for a while, disaster was liable to occur quite suddenly and unexpectedly. The best result was obtained by resection and anastomosis, but this could only be carried out when the disease was definitely limited and the situation was favourable. As a rule, however, resection was not possible, and colostomy had to be performed. Wrapping the diseased area carefully in omentum might obviate colostomy, but again this could only be done if the inflammatory process had not spread and the stricture formation was not well advanced. Abscess and fistula formation necessitated colostomy. In a few instances it had been possible to resect the bowel six to eight months later, when the inflammation had subsided, but the operation was usually extraordinarily difficult. If the patient wished to avoid colostomy the involved area could be short-circuited, appendicostomy being performed to keep the blind loop clean. The paramount importance of early operation in preventing complications in all cases with established inflammation was strongly urged. The speaker had seen cases of diverticulitis complicated by carcinoma, and on three occasions he had observed carcinoma developing apparently as the direct result of diverticulitis.

Mr. SEYMOUR BARLING (Birmingham) said that to the surgeon the disease most frequently presented itself as an emergency. Then the simplest procedures of drainage or colostomy should be carried out. In the less acute stages of the disease there were two points worthy of consideration. First, the disease was of slow progress, but nevertheless there was always the possibility of a sudden disaster occurring, and careful supervision was necessary to detect any deepening of symptoms. Secondly, there was always great technical difficulty in removing the affected area of the colon. Resection was advisable in carefully selected cases for repeated inflammatory attacks, threatened obstruction, or fistula formation. Mr. Barling described a case with an inflamed and irritable colon on the left side, in which he saw the sudden projection of thin transparent finger-like processes from the bowel wall as the result of violent contraction. After the spasm passed the protrusions withdrew into the thickness of the bowel wall. Spasm and inflammation appeared to be the essential underlying causes of the fully developed condition. Inflammation of the colon was the primary and essential condition, diverticula, though usually present, being concomitants of the disease. He had excised a portion of colon resembling diverticulitis, in which there were no diverticula. He had had two cases of diverticulitis associated with papillomata. Mr. GARNETT WRIGHT (Manchester) agreed with Mr. Seymour Barling concerning the emergency surgery of the condition. He said that inflammation and perforation of only one diverticulum had produced peritonitis and also vesico-colic fistula. One case was described in which the colostomy which was performed for acute intestinal obstruction was successfully closed after the inflammation had subsided. Professor WILKIE (Edinburgh) said it was essential to draw a clear distinction between diverticulitis and diverticulosis. X-ray evidence should be carefully interpretated in correlation with the clinical signs and symptoms. The surgeon was usually consulted for one of three conditions: (1) Acute symptoms comparable to acute appendicitis on the left side. Usually in these cases expectant treatment with local heat and petroleum by the mouth was indicated; occasionally, however, immediate operation for perforation was imperative. (2) Subacute obstruction of the colon. Here colostomy might be needed. (3) A group in which chronic toxaemia was an outstanding feature. Cholecystitis was also frequently present, probably as a secondary infection. The patients were usually unsuited to surgical intervention, and expectant treatment and liquid paraffin were indicated. In very few instances was it possible to resect the diseased area. The crux of the operative question was whether the diverticulitis did or did not extend so low down as to render resection unjustifiable. Preliminary colostomy was safer, and the results had been most gratifying.

Dr. SPRIGGS, in reply, said that the diverticula protruded through gaps in the muscle and did not follow the track of vessels through the bowel wall. Their formation was usually preceded by the prediverticular state. He said that the earliest stages could not be seen, as they were analogous to auricular fibrillation. He felt that many catastrophes could be avoided by examination by means of opaque enemas every six months. Care should be taken not to mistake the condition for neurasthenia.

SCOPE OF RECONSTRUCTIVE PLASTIC SURGERY.

Mr. T. P. KILNER gave an extremely interesting and instructive demonstration, with lantern slides, of the methods and results of reconstructive plastic surgery. Excellent results were shown of pressure Thiersch grafting in the mouth and elsewhere. The uses and results of many methods of plastic surgery. Wolff grafts, pedicle grafts, bone and cartilage grafts, were demonstrated. Mr. Kilner said that excision of a severe *x*-ray burn relieved the pain, and the results of grafting in extensive burns of the neck and hand were shown. The use of fat grafts for filling depressions due to fractures or bone loss on the face were strikingly illustrated. It was impossible to describe adequately the wonderful results obtained by rhinoplasty and by the "Cupid's bow" operation in hare-lip. He appealed

to surgeons to avoid stitch marks on the neck and face, as these were singularly tedious to deface.

A new instrument for cutting cranial bone flaps was shown by Mr. Lambert Rogers (Cardiff). The essentials were a pistol grip carrying the saw, a dura mater guard, and a small electrically driven circular saw. The saw was controlled by a thumb push and by the pistol grip. A number of lantern slides were shown demonstrating its use. The following advantages were claimed: (1) flaps of any size or shape could be cut; (2) the brain and meninges were protected; (3) did not jar or concuss the patient; (4) an opening in the centre of the flap was not necessary—an undesirable procedure in the case of a vascular meningeal tumour with underlying bony changes; (5) flaps could be turned down rapidly and easily.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

Wednesday, July 24th.

Chronic Cervicitis.

The President, Professor Fletcher Shaw, in welcoming the members of the Section, referred to the work done in Manchester in advancing the cause of medical education, especially in their own branch. The Manchester school was the first to obtain recognition from the examining bodies and to break down the monopoly of the London schools. He mentioned some of the great gynaecologists who had helped to make the Manchester school famous. Charles Clay was the first to perform ovariotomy, and was the first surgeon to perform hysterectomy for fibroids. His name was little known, but he had done much pioneer work in gynaecology.

The subject for discussion at the first meeting was chronic cervicitis (leucorrhoea). The opening paper was contributed by Dr. John Barris, who reviewed the subject from the point of view of etiology and symptoms. The condition, he said, was one of the commonest met with in both hospital and private practice. Chronic cervicitis might be defined as an inflammatory affection which involved the mucous membrane of the cervical canal and of the os uteri externum. It was characterized by leucorrhoea and the presence usually, but not invariably, of a cervical erosion. It was due to infection, and was accompanied by microscopic signs of inflammation. Dr. Barris sketched the development and anatomy of the normal cervix, pointing out the various types of epithelium met with in different parts of the canal. In the normal vagina the upper part was sterile, due, it was supposed, to the presence of an acid medium hostile to the growth of pathogenic organisms. Invasions of organisms might be due to direct infection as in the case of the gonococcus, or by indirect infection following injuries to the cervix at childbirth. Chronic cervicitis was very common, particularly between the ages of 30 and 40, the child-bearing age. The chief symptom was leucorrhoea. General debility, anaemia, and constipation were not unusually accompanying symptoms. Sterility might result. Disorders of menstruation and backache did not occur unless the infection involved the endometrium or the uterine appendages. Finally, cervical trauma and erosion might be associated with malignant disease.

Dr. Gilbert Strachan (Cardiff) dealt with the pathology of chronic cervicitis. It was, he said, the commonest lesion by far met with in gynaecological practice. British gynaecologists had not devoted the attention to the subject which it deserved or such as had been given to it by their colleagues in America and on the Continent. As regards the infective process the most usual mechanism was chronic pyogenic infection after laceration of the cervix in childbirth. In his opinion the incidence of gonorrhoea as a causative agent was exaggerated. The erosion of the cervix was not an ulcer nor yet a granulating patch; it was an epithelial covered surface, though there was often a breach of continuity between the two types of epithelium at the periphery of the erosion. Discussing the late results of cervicitis Dr. Strachan said that these were many and important, and might be grave. Infiltration of the parametrium and later fibrosis might be produced by lymphatic extension. The utero-sacral ligaments were often involved, and pain was produced in the lower part of the back by pulling the cervix forwards. These parametrial extensions were the commonest causes of backache or chronic pelvic pain in women. He thought the effect of the discharge in bringing about mental disease had probably been exaggerated. Pruritus vulvae might be caused by the constant irritating discharge, but the most important sequel was carcinoma. About 96 per cent. of carcinomas of the cervix occurred in parous women. Nulliparae with congenital or gonococcal erosions were not predisposed to carcinoma, so they were forced to the conclusion that it was not the erosion but the damage to the cervix associated with it which was the predisposing factor.

Dr. R. S. Statham (Bristol) devoted his paper to the treatment of cervicitis, and as the methods advised were so numerous and diverse, he expressed merely his own personal preferences. He commented on the frequency with which thickening and inflammation of the cellular tissue at the base of the broad ligaments gave rise to pressure upon and nipping of the ureter, producing chronic backache and renal pain. He pressed for the early treatment of all lacerations of the cervix, and for all established erosions. Laceration of the cervix during childbirth should be properly repaired as soon as it occurred. He was convinced *that gonorrhoea was far more commonly at the bottom* of cervical infection than was usually thought. He believed that if the presence of the gonococcus had been demonstrated, and *in all early cases, there was no treatment so good* as daily douching with boric acid, followed by thorough swabbing of the cervix and vaginal vault with 1 per cent. mercurochrome. This treatment could only be adequately carried out by an attendant. If severe laceration were present, with spread of infection into the pelvic cellular tissue, then he had found really hot and prolonged douching the most efficient remedy. The douche should be as hot as could be borne, and should be continued for at least fifteen minutes. Glycerin or glycerin and ichthyol tampons were only of use when applied by a skilled nurse, otherwise they were positively harmful. He *condemned* the practice of putting in ring pessaries to relieve backache; they only tended to keep up the cervical infection, and pressed upon tender fornices and ureters. For chronic and persistent cases there was no question but that the treatment must be operative. For some time past he had been using the electro-cautery with the greatest success. When the endocervicitis was complicated by laceration the operations possible fell into three groups: (*a*) repair operations, (*b*) amputation of cervix, and (*c*) panhysterectomy. He was not in favour of amputation in young patients, rather reserving this operation for women who were not likely to have more children. In elderly patients, especially if there was reason to suspect fibrosis, panhysterectomy was certainly the operation of choice. In this connexion he spoke very favourably of operation by the vaginal route.

The President, in declaring the discussion open, said that the subject had been chosen as the condition was so common and the treatment was generally so unsatisfactory. Dr. James Young (Edinburgh) emphasized the amount of abdominal and pelvic pain which might follow on infections of the cervix. In the majority of cases there was some spread into the parametrium, and there was no condition so likely to cause low abdominal distress as chronic cervical infection. If that were recognized much good could be done in giving relief. He advocated freely opening up the cervix by means of the cautery. The common site of the pain was the left lower abdomen. Much chronic invalidism, such as persistent arthritis or chronic heart disease, could be traced to cervical infection. He asked about the frequency of involvement, and especially stricture, of the ureter. In his own experience this was rare, and he thought its importance had been overestimated.

Professor Cullen (Baltimore) said that early in his career he had been interested in the histology of the cervix. They did not get very many cases of true erosion. He had never seen ciliated epithelium in the cervix. In regard to treatment there was naturally much difference of opinion. He thought that prolonged irrigation was of very great value; mercurochrome had given great satisfaction. They should remember that many cases with gonorrhoeal infection became reinfected. Repair of one

side of a lacerated cervix was often sufficient. He did not approve of vaginal hysterectomy in prolapse, as it involved removing the keystone of the arch supporting the abdominal and pelvic viscera. In regard to ureteral stricture, Hunner was a pioneer, and, like all who were in advance of their time, was going through the stage of being discredited. He thought stricture of the ureter was more common than was realized. Dilatation of the ureter was often a godsend in giving relief.

Mr. L. C. RIVETT was a little doubtful about carcinoma being a sequel to chronic cervical infection. His experience did not bear this out. He found the cases of very profuse discharge the most difficult to deal with. These cases did clear up with swabbing, but nearly always recurred. He believed that gonorrhoea was responsible in nine cases out of ten. Dr. BETHEL SOLOMONS (Dublin) thought that the discussion very clearly brought out that no cure of these cases was possible by other than definitely surgical methods. Prolonged treatment with douches and swabbing was merely a waste of time. He could not see how they could escape from the conclusion that carcinoma was frequently a sequel. He was doubtful about advising immediate repair of lacerations by all and sundry; it would add enormously to the risk of childbirth. In regard to sterility, it was difficult to say whether it was the cervicitis or salpingo-oöphoritis which was responsible. He did not think very highly of mercurochrome or brilliant green. Leucorrhoea might almost be normal in some women. Unless it caused definite trouble he did not think it should be considered. Treatment with the cautery was a waste of time. He had never seen any ill results from amputation of the cervix. Hysterectomy should only be considered as a last resort. Dr. FORBES (Aberdeen), speaking as a general practitioner, thought that all cases of leucorrhoea could not be due to inflammation of the cervix. In regard to left iliac pain, he had been taught many years ago that it was due to inflammation in a band of tissue running from the cervix to the pelvic wall. Many cases of bacilluria were due to a stricture of the ureter. Professor LOWRY (Belfast) agreed with the view that the cervix was a very important focus of general infection such as rheumatism. It was often impossible to demonstrate the gonococcus when on clinical grounds one was certain that it was the causative organism. Often women with very profuse leucorrhoea had babies; he did not consider it was a frequent cause of sterility. He spoke favourably of mercurochrome. He was strongly against teaching students that immediate repair of the cervix was advisable. Lysol was one of the most pernicious things to use as a douche; he was against indiscriminate douching altogether.

Dr. K. V. BAILEY (Manchester) thought that by pure histological means the connexion between lacerations of the cervix and carcinoma could be definitely demonstrated. Dr. RIDDELL (Plymouth) felt that traumatism was the commonest cause of cervicitis. He hoped that the term "erosion" would be dropped entirely. He suggested that a time limit should be imposed for medical methods of treatment—say, six months; surgical treatment should then be considered. He thought that vaginal hysterectomy was a step in the wrong direction; fewer mistakes would be made if the abdominal operation were performed. He did not agree that cervicitis was the cause of the one-child marriage, and he did not think that a case had been made out for the causation of carcinoma by cervicitis. The question of focal infection was a very important one indeed.

Dr. FARQUHAR MURRAY (Newcastle) laid emphasis on the point that in a large number of patients who came complaining of leucorrhoea there was no evidence of any inflammatory process. He strongly protested against indiscriminate douching without a careful preliminary examination. It was highly important to treat any concomitant urinary infection. Pain might be due to the urinary infection. It was not practicable or advisable to teach immediate repair of cervical lacerations. It would be most highly dangerous to attempt immediate repair of a high laceration spreading above the vault of the vagina. Regulation of the bowels was of supreme importance in all these cases. At this stage the discussion was suspended for a few minutes while the President of the Association, Mr. A. H. Burgess, addressed a welcome to the Section.

On resuming, Mr. KENNETH FOSTER (Worcester) thought there was no doubt that the cause of most cases of cervicitis was trauma at confinement. He pleaded for more care to obviate the use of forceps. Proper ante-natal care was supremely important. Professor MAXWELL (Pekin) said that a few years ago he stopped all douching, except for those patients who were actually attending the hospital. They had picked up ten cases of early cancer recently by examining patients in whom the discharge had not quickly cleared up after this intensive douching. Professor DOUGAL (Manchester) wanted to know how to treat a case of constant discharge. Attention to general health would clear up discharge in young patients. It was a different proposition when the discharge was largely pus. Here rest, heat, and raising the general powers of resistance were the lines of treatment. The PRESIDENT thought the question of general douching had at least been settled for good at this discussion. They had heard very little about cauterization and diathermy; he had treated a number of patients this way during the past year, but he was disappointed in his results. It was important to improve the general health of the patient.

Dr. STATHAM, in reply, pointed out that the cases in which he advocated vaginal hysterectomy were those of elderly women with profuse bleeding who required repair of the perineum. He agreed that medical treatment wasted a lot of time, and he would limit it to six months. Dr. STRACHAN agreed with Professor Cullen that he had never seen ciliated epithelium in the cervix. The cervix as a source of focal infection was of great importance. The changes in cervicitis were certainly definite histological changes. He thought there was little evidence of the connexion between cervicitis and sterility.

SECTION OF DISEASES OF CHILDREN.

Wednesday, July 24th.

TUBERCULOSIS IN EARLY CHILDHOOD.

Dr. C. P. LARAGE, President of the Section, took the chair at its first meeting.

Dr. C. McNEIL (Edinburgh) referred sadly to the fact that the late Professor Pirquet should have introduced this subject. He added a brief comment on the great contribution made by Pirquet to the elucidation of the problems of tuberculosis in childhood. In a survey of the first five years of life Dr. McNeil showed how the number of deaths during this period from tuberculosis greatly exceeded those in the later period of childhood and of puberty. Meningitis was easily first as the most frequent form of fatal tuberculosis at this age period, while the number of cases of pulmonary tuberculosis and abdominal tuberculosis was about equal. Cases of surgical tuberculosis only added a small contribution to the number of deaths at this period, while examples of disseminated tuberculosis amounted to a considerable total. Dr. McNeil then presented in tabular form a survey of 254 cases of tuberculosis admitted to his wards during the past eight years, including both non-fatal cases and the results of post-mortem examinations. He did not agree with the common statement that the Pirquet test often failed in tuberculous meningitis and in general tuberculosis: if properly performed this was not so, and during the first two years of life he regarded a positive tuberculin reaction as of great value in diagnosis and of grave significance. A negative reaction was of value in the later periods of childhood in excluding tuberculosis, while the positive test was of less help in diagnosis. Dr. McNeil next discussed the problem of latent tuberculosis; he stated that in the first two years of life tuberculous infection nearly always proceeded to tuberculous disease, and this disease in nearly all cases ended in death. This should enable physicians to rid themselves of the haunting fear of latent tuberculosis in the early years of childhood, at which period the problem of diagnosis was the discovery of active disease in the thorax or abdomen. Tuberculous meningitis was a secondary manifestation, being the end-result of an earlier focus of disease. Post-mortem results warranted the general statement that the primary focus was glandular or visceral, either thoracic or abdominal, in nearly all cases

with a clear majority of thoracic origin. Dr. McNeil next discussed some of the problems of diagnosis in pulmonary tuberculosis when difficulty was especially likely to be present during the first two years. At this period four varieties were common: tuberculous bronchitis becoming broncho-pneumonia, acute caseous pneumonia, chronic fibroid pneumonia with cavities, and a caseous process at the hilum of the lung spreading into it. The first two occurred at an age when bronchitis and lobar pneumonia were both common, and gave the same physical signs, whether simple or tuberculous. In the tuberculous forms the onset was insidious with less general distress and dyspnœa, while the course was quiet, leading on to loss of weight and pallor. *X*-ray examination, a positive sputum test, and a positive tuberculin test were all of great value. The most difficult to diagnose was the type beginning at the hilum, and often signs of a severe progressive toxæmia were the only manifestation. Summing up these cases, Dr. McNeil again insisted that at the early period of childhood healed tuberculosis in glands or in the lungs was very rare. With regard to abdominal tuberculosis, he pointed out the interesting local variations which occurred: in northern England and in Scotland this form was still a grave problem, and was a reliable index of widespread infection of the milk supply with tubercle bacilli. Turning lastly to the question of preventive measures, Dr. McNeil laid it down that the greatest impetus towards the success of such measures was the conviction of the medical mind that the disease was a contagious one. The fact of contagion from another human being, and the fact of the transmission of the disease from milk to man, were of greatest importance in childhood. The problem of tuberculous milk in relation to tuberculosis in children was complicated, and in some areas, including Manchester, there had lately been an increase in the samples of such milk obtained. There appeared to be no generally agreed policy with regard to such milk, and even the medical profession was not agreed as to the necessity for boiling milk. Finally, Dr. McNeil dealt with the human source of tuberculosis, and indicated how detection of pulmonary disease in the adult and the prevention of close contact with the children were the important steps to be taken in order to cut down the occurrence of tuberculosis in early childhood.

Dr. HUGH THURSFIELD, who discussed the difficulties of diagnosis of tuberculosis, first in infants, and secondly in children of school age, said that in infants the main difficulty lay in distinguishing between a tuberculous broncho-pneumonia, a simple broncho-pneumonia, and an empyema. Acute miliary tuberculosis of the lungs was easier, on the whole, although the so-called typical *x*-ray pictures did not always occur. Dr. Thursfield then illustrated the various types of diseases in the thorax which gave rise to difficulty by means of lantern slides. He said that the term "epituberculosis" was a useful one, and for him meant the sort of case in which consolidation of the lung was present in association with a tuberculous focus, and yet was not in itself tuberculous in character, and therefore capable of resolution. He emphasized several points which facilitated diagnosis: a history of contact, a palpable spleen, and the enlargement of the lymphatic glands of the thoracic wall were all of great help; it was also of great importance to puncture the chest with an exploring needle if there was any doubt about the diagnosis in a chronic case. The tuberculin skin reactions did not appear to give much assistance. With regard to the diagnosis of tuberculosis in older children, he thought the disease was far too often said to be present in the chest when actually all that was present was evidence of healed mediastinal glands, which were not a frequent cause of ill health.

Dr. JAMES M. SMELLIE (Birmingham) based his remarks on his experience of 1,190 post-mortem examinations during the last seven years. In 182 cases death was due to tuberculosis, which was approximately 15 per cent. of the autopsies. The peak of the mortality occurred in the second year of life; the seasonal incidence showed that the highest occurrence was in the period from January to April, and the lowest in August. In 33 per cent. of cases the mediastinal glands were the only ones involved, in 31 per cent. both mediastinal and mesenteric glands were infected, while in 17 per cent. only the mesenteric glands had become affected, and it might be deduced that in about two-thirds of all cases the infecting organism was the human tubercle bacillus. Dr. Smellie emphasized that latent tuberculosis was a very rare lesion to find at autopsy, and under 5 years of age the disease seemed to run a very rapid and fatal course in most cases. He pointed out the importance of tuberculous otorrhœa as a symptom in some cases. In dealing with the question of treatment it was obvious that this must centre round prevention, and in this connexion he remarked on the studies of immunity in relation to other infections, such as diphtheria, where subminimal doses brought about an increased resistance, and it was along these lines—as, for example, by the use of the B.C.G. vaccine—that hope for the future lay, as well as in building up the general health of the child.

Dr. STANLEY MELVILLE emphasized the point that in nearly all cases the primary lesion in tuberculosis in children lay in the lung parenchyma; from this the glands in the mediastinum became involved secondarily. If the initial infection was massive an acute caseating broncho-pneumonia or miliary tuberculosis developed, but if resistance was higher or the infection less, then either hilum tuberculosis or the adult and more chronic type of the disease resulted. He regarded the diagnosis of hilum tuberculosis as a purely topographical one, and he thought that both radiologists and clinicians had allowed themselves to become overwhelmed by the size of the shadows produced in the mediastinum. He urged that when an *x*-ray picture was examined the hilum be covered up for a correct estimation of the extent of the disease to be ascertained. Dr. HUGH ASHBY (Manchester) said that he always had difficulty in diagnosing tuberculosis in children. He had given up the skin tests, and attached very much more value to the ordinary clinical signs and to an *x*-ray photograph of the thorax wherever the situation of the suspected tuberculosis might be. He thought that empyema presented a very real difficulty; needling should always be employed in a doubtful case.

Dr. C. CHISHOLM (Manchester) gave her experiences in tuberculosis in infancy, basing her remarks on 3,500 cases of digestive disorders and wasting, where the diagnosis of tuberculosis had been made in 130 instances. Out of these cases the diagnosis had been established in only 50 cases, among whom 72 per cent. had died. A history of contact among members of the patient's family was very commonly found. She pleaded that a strong stand should be made for obtaining a pure milk supply, and that the profession should not be satisfied with sterilization and pasteurization. In 10 per cent. of all cases admitted to her care a positive skin reaction to tuberculin had been obtained. Dr. E. A. SAUNDERS emphasized the value of close co-operation between the radiologist and the clinician in these cases. He thought that segregation of open tuberculosis cases was an important means of prevention; the danger of creating a virgin-soil population in this way was exaggerated, since even those children thus separated from their parents were exposed to subminimal doses in everyday life.

The President, Dr. C. P. LARAGE, thought that he was seeing fewer cases of tuberculosis now than formerly, and that recent measures of tackling the problem were already bearing fruit. Tuberculosis was very infectious to young children, and they might be endangered, not only by open cases, but also by such cases as tuberculosis of the hip. He remarked on the relation of injury to the onset of tuberculosis in the hip and meningitis cases, and inquired what was implied by this. Professor C. W. VINING (Leeds) spoke of certain other forms of tuberculosis in early childhood, instancing generalized glandular tuberculosis and tuberculosis of the ear; he thought the prognosis in the first of these was good. He also mentioned the problem arising in children under the age of 3 where signs at one apex gradually but very slowly disappeared. He commented on the difficulty of finding tubercle bacilli in the sputum, and also of the radiological picture in thoracic tuberculosis where only the miliary, and possibly the broncho-pneumonic, types gave rise to a characteristic appearance. He did not think that infected glands at the root of the lung could be diagnosed in this way.

SECTION OF PHYSIOLOGY AND BIOCHEMISTRY.

Wednesday, July 24th.

PHYSIOLOGICAL TESTS OF RENAL FUNCTION.

PROFESSOR RAPER, the President of the Section, took the chair, and Professor E. B. VERNEY opened the discussion with a paper which is printed in full at page 179. Sir WILLIAM H. WILLCOX examined as a routine the volume of urine passed in twenty-four hours, together with its percentage content of urea and chlorides. The most valuable test was undoubtedly the estimation of blood urea; it was of special value in showing whether defective renal function played any part in toxaemic symptoms such as occurred in advanced heart failure or in acute infections. Cases were quoted of blood urea figures over 100 mg. per cent. in diphtheria. In one case of acute alcohol poisoning 330 mg. per cent. was observed; the patient made a complete recovery. In congenital cystic kidney extremely high values might be obtained, although the clinical history might be very short. Attention was also drawn to cases of *B. coli* infection with sudden convulsions, in which the estimation of the blood urea was of value. Caffeine citrate was of value in some cases of chronic nephritis, but it sometimes ceased to have any diuretic action after two or three days.

Professor E. C. DODDS laid stress on the importance of estimating not only the urea, but also the non-protein nitrogen, the cholesterol, and the total protein of the blood. Thus the two latter may be much altered in non-oedematous cases where there was little or no evidence of nitrogen retention. These estimations were of value in deciding whether a patient would or would not benefit from a high protein diet. If the cholesterol and protein were normal this treatment would be of no value. Since a low blood urea did not certainly exclude uraemia, the estimation of calcium and phosphorus was of value. If the calcium was reduced to 5 or 6 mg. per cent. and the phosphorus raised, the prognosis was grave. Stress was also laid on the importance of "dehydration," as in vomiting, as a cause of high blood urea. The estimation of the total solids of the blood would reveal this state.

Professor J. SHAW DUNN (Manchester) gave an account of experimental oxalate nephritis in animals. The subject was difficult, because a nephritis severe enough to cause oedema usually killed the animal. The urea output and concentration of normal rabbits were compared with those of nephritic animals on a series of lantern slides; the concentration of urea was definitely impaired. If these rabbits were fed on a dry diet their weight fell, their blood urea rose, and in some cases the animals died of uraemia. This occurred over two hundred days after the production of nephritis, when the animals had apparently reached a steady state. Professor Shaw Dunn suggested that this observation might be of practical value in therapeutics. Mr. H. D. KAY gave an original method of testing renal function: 550 mg. of sodium β-glycero-phosphate was injected intravenously, and the urine excreted during the following hour was analysed for phosphate and compared with a specimen taken the hour before. A normal man would excrete at least 150 mg. extra phosphate; a severe case of nephritis would sometimes excrete none. Over sixty cases of renal disease had so far been examined, and this new test appeared to conform with clinical and post-mortem findings more closely than the phenol sulphonephthalein or the urea concentration test. The other advantages were that the substance was harmless and easy to obtain and to sterilize; the ward preparations were simple; there were two urine analyses to perform and no blood analysis; the presence of blood or of urine pigment did not disturb the test. Mr. J. B. MACALPINE (Manchester) dwelt on the importance of desiccation of the tissues resulting from polyuria, and the necessity of waiting in cases of enlarged prostate until the blood urea came down again after cystostomy before proceeding with the major operation. He also mentioned the importance of avoiding catheterization of a healthy ureter across an infected bladder; the indigo-carmine test enabled this to be achieved. The blood urea estimation was of the utmost value, and, in addition, he always employed the urea concentration test. A series of slides were shown to illustrate the great value of pyelography. Dr. F. H. SMIRK (Manchester) said that the effects on the urinary composition of administering either water, urea, or caffeine by mouth to normal individuals differed sufficiently from the responses of patients with defective kidney function to be of value as tests of renal inadequacy. The renal elimination of water under stress, when one litre of water had been administered by mouth, was found inadequate in all nephritics examined, including interstitial nephritis with polyuria. The effect on the renal salt excretion of administering urea was a practical and useful test of renal function, and had the advantage that a urea concentration test was simultaneously performed; 18 of 22 normals (yet only 2 out of 55 patients with Bright's disease) attained a urinary percentage NaCl of 0.8 after giving urea by mouth. Normal individuals failing to attain the 0.8 per cent. NaCl were readily distinguished by the considerable increase in salt concentration after administration of urea: 17 out of 18 nephritis cases with normal urea concentrations were detected by this test. The NaCl percentage usually increased in diuresis produced by urea and caffeine. The total amounts of other excreted substances were usually increased in varying proportions after administration of these drugs, but their concentration varied almost inversely as their diuresis.

Dr. E. P. POULTON held the view that caffeine produced an increased glomerular filtrate so that the excretion of chloride was increased; urea did not produce this effect. The urea concentration test in its most common form was criticized, because, by ignoring the total quantity of urea excreted, half the information obtainable by the test was lost. He showed numerous analyses obtained from patients to illustrate this point. With regard to oedema, Dr. Poulton considered that the causation was not always due to a fall in serum proteins, because examination of these immediately before and after a diuresis showed no change. He did not attach much importance to dehydration as a cause of high blood urea, considering that, in addition to this, the kidney must be deranged to account for such high figures as had been mentioned after vomiting. He suggested that Dr. Kay should compare the new glycerophosphate test with the urea test in its best form. Mr. SWIFT JOLY spoke of the importance of following the urea excretion over several hours. He discussed the observation of American surgeons that hypertrophy of one kidney usually meant complete failure of the other.

In reply, Professor VERNEY congratulated Mr. Kay on the test he had described. He considered that as at the present moment there was such disagreement among physiologists about the precise location of the functions of the different parts of the renal unit, it was probably desirable to consider these units together, and not to dissociate the functions of tubule and glomerulus. With regard to caffeine, this drug increased the effectiveness of the kidney stimulus to excretion: when it was administered an adequate quantity of water should be given at the same time. In conclusion, Professor RAPER thanked those who had contributed to the discussion. Although no general decision was at present possible, yet it was to be hoped that the stimulus received from the interesting communications which had been given would lead to more work on this important subject.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

Wednesday, July 24th.

RELATION OF MALIGNANT DISEASE TO BENIGN TUMOURS IN THE INTESTINAL TRACT.

PROFESSOR M. J. STEWART (Leeds), in opening the discussion, reviewed the various kinds of simple tumours that occurred in the alimentary tract, and discussed the incidence and the nature of the malignant changes to which each was liable. Simple connective tissue tumours were comparatively infrequent, the only two of any importance being lipoma and leiomyoma. Submucous lipomas were rare and were mostly mere casual findings at autopsies. Subserous lipomas were frequent, but neither type of tumour underwent malignant change in the intestinal tract. Leiomyomas were much more common; they were found chiefly in the stomach and oesophagus; they were

flat sessile growths, which grew slowly and seldom reached a large size. As with uterine fibroids, alimentary tract leiomyomas occasionally became sarcomatous, but as the latter were usually single tumours it was often difficult to decide whether they had begun as simple tumours or had shown malignant characteristics from the start. The simple epithelial tumours, however, were clearly the most important of the group under discussion, for they were with good reason suspect as precancerous lesions. They were generally adenomatous in structure; starting as small flat patches, they rapidly became polypoid and showed a remarkable tendency to multiplicity, especially in the large intestine. The muscularis mucosae was dragged inwards with the rest of the mucous membrane, and was frequently thickened. The presence of an intact muscularis mucosae unbreached by epithelium was the best evidence that a polyp had not become malignant. Definite connexion between simple adenoma and carcinoma of the intestine had now been established, and in this connexion Professor Stewart mentioned briefly Dr. Dukes's statistics. With regard to the stomach, too, opinion was hardening in the same direction, and his own experience afforded further evidence of the sinister significance of ostensibly benign growths. In 11,000 necropsies during nineteen years at the Leeds General Infirmary, gastric polypi were found in 47 (0.43 per cent.); in 13 of these (28 per cent.) carcinoma of the stomach was present in association with the polypus. The total number of cases showing carcinoma of the stomach was 263. In his view simple adenomatous polypi of the stomach, whether single or multiple, must be accepted as a definitely precancerous lesion. Adenomyoma and pancreatic heterotopia occurred in the stomach, duodenum, and small intestine, but there was no evidence that they were specially liable to malignant change. Carcinoid tumours of the appendix and small intestine, like rodent ulcer of the skin, occupied an intermediate position between the simple and malignant tumours; but there was no evidence that these tumours underwent the malignant metamorphosis under discussion. Professor Stewart ended with a brief reference to experimental pathology.

Professor A. LEITCH considered that the experience of any single pathologist in respect of epithelial tumours of the small intestine was unlikely to be sufficiently extensive to enable him to define a relationship between benign and malignant tumours. He himself had seen only two carcinomata, one a small pedunculated growth in the third part of the duodenum with extensive metastases, and the other an annular carcinoma low down in the ileum. He had seen one simple sessile adenoma of the jejunum with no suspicion of malignant change. His personal experience of tumours of the large intestine, especially rectum and pelvic colon, owing to his association with Mr. W. Ernest Miles and his colleagues, had been possibly unique. In attempting to associate carcinomata with simple epithelial growths there were two points to be considered: (1) the frequency with which one or more of a series of multiple adenomata showed malignant change, and (2) the frequency with which a well-defined carcinoma was accompanied by satellite papillomata. In both cases it was impossible to arrive at a definite figure, for the reason that we had no control observations. His own strong impression was that definite multiple adenomata were very liable to become malignant, and he showed several instances in the museum. On the other hand, he could not agree with the thesis sustained by Dr. Dukes that frank carcinoma was accompanied in any large percentage of cases by simple tumour formations. It was a thesis with which he, as an experimentalist, was in sympathy, but actual analysis of museum specimens was against it. Taking 50 consecutive cases of cancer of the rectum or pelvic colon, and examining the specimens with a lens, he found that 40 had no papillomata or hypertrophic patches, 2 had pedunculated adenomata, 3 had one or more warts not exceeding the size of lentils, and 5 showed pinhead-sized plaques, but whether those "plaques" were as commonly found in normal rectums no one could say, but he would attach no importance to them. He would be inclined to say that no more than 15 per cent. of rectal cancers were accompanied by papillomata.

Dr. CUTHBERT DUKES classified his last 75 specimens of carcinoma of the rectum into three groups: "A" cases where the cancer had only infiltrated the submucous coat, "B" cases where it had penetrated into the muscular coat, and "C" cases where it had spread by direct continuity into the perirectal tissues. He had only one "A" case in this series, and this was associated with papillomata; of 18 "B" cases, 9 (50 per cent.) were associated with papillomata; and of 56 "C" cases, only 17 (30 per cent.) were associated with papillomata. The conclusion was that papillomata were commoner in early than in late cases of cancer, and that the occurrence of papillomata could not depend on the irritating discharges of an ulcerating growth, but that they represented the response to an irritant acting over a far more extensive area of mucous membrane than that which ultimately bore the malignant growth. The comparative rarity of papillomata associated with "C" cases suggested that some sort of immunity developed as the result of malignant invasion with retrogression of the epithelial proliferation in the immediate neighbourhood. With regard to the figures Professor Stewart had quoted from an earlier paper, Dr. Dukes said that in his present series he was reporting only cases where the papillomata were visible at first glance; in the previous series the mucous membrane and mucosa had been dissected away from the muscle, and by this method a much larger proportion of cases of papillomata had been recorded. Dr. SUSMAN (Manchester) said that in 883 autopsies investigated, 38 cases (4.3 per cent.) showed polypi of the colon. There were 25 males and 13 females; the average age was 57. Polypi were associated with gastro-intestinal cancer in 14 cases, and in 3 cases with carcinoma elsewhere, suggesting that polypi of the colon were frequently associated with gastro-intestinal carcinoma. Carcinoma of polypi was observed in 4 cases of carcinoma of the colon, all cases showing multiple polypi. Carcinoma of the colon appeared to follow on polypi of the colon in many cases. In all there appeared to be a common cause for gastro-intestinal cancer and polypi. The condition had a distinct male preference.

Dr. J. S. YOUNG (Leeds), after a brief reference to his own experiments in the production of epithelial hyperplasia following intrapleural injection of Sudan III dissolved in olive oil and emulsified with bile salts, recalled the work of Stoeber and Walker, who demonstrated an irregular type of epithelial proliferation following the injection of indole and skatol. These substances were derivatives of the bacterial disintegration of tyrosine and tryptophane, and it was suggested that under certain conditions the bile salts in the chyme might facilitate the action of these products in stimulating simple epithelial hyperplasia. Whereas, however, it had been easy to provoke such hyperplasia experimentally by a great variety of biologically active substances, it had not been possible by a single injection to determine a pregressive malignant growth.

Dr. C. E. JENKINS (Salford) recalled the fact that *B. coli* produced phenol, and questioned whether it might not produce more complicated substances of the same order with possible carcinogenic properties. Professor CRUICKSHANK (Aberdeen) criticized Dr. Dukes's evidence that retrogression of the papillomata occurred during malignant invasion of the tissues. A paper was read by Dr. D. F. CAPPELL of Glasgow on the reticulo-endothelial system studied by intra-vitam staining.

SECTION OF OTO-RHINO-LARYNGOLOGY.

Wednesday, July 24th.

INFLAMMATORY INTRACRANIAL LESIONS.

At the first meeting of the Section the subject of discussion was the cerebro-spinal fluid as an aid to the diagnosis and treatment of inflammatory intracranial lesions. Mr. F. H. WESTMACOTT was in the chair. The opening paper was read by Dr. WELLS P. EAGLETON (Newark, New Jersey), and was of an altogether exceptional character. The speaker first traced the development of the meninges, and then described the basal cisterns which were in relation with the arterial supply—the basilar and external carotid arteries.

The prolongations from the internal auditory meatus into the cisterns were extremely small, thus limiting the rapid spread of inflammation. The meshes of the cortical arachnoid, on the contrary, were related to the veins, and the cerebral veins, unlike the arteries, had no outer fibrous coat, so that a spreading thrombophlebitis was very virulent, for the outer layer of these veins was formed by the arachnoid itself. The cerebro-spinal fluid came from all the vessels, and seemed to contain a ferment in addition to glucose and chlorides. Increase of pressure meant irritation of the arachnoid, the disappearance of glucose meant its consumption by organisms, and the reduction of chlorides showed that the barrier between the blood and the cerebro-spinal fluid was breaking down. Dr. Eagleton brought many other points forward, an original one being that an early sign of increased intracranial pressure was a lack of response by the vestibular apparatus to the caloric test in the upright position, whilst nystagmus was produced normally in the horizontal position.

Dr. J. G. GREENFIELD described the chemical characters of the cerebro-spinal fluid in relation to meningeal and cerebral lesions. Dr. HENRY COHEN (Liverpool) insisted on the importance of the chemical investigation of the cerebro-spinal fluid, the fluid tending towards the composition of the plasma in inflammation, so that chlorides fell while phosphates and uric acid rose. The presence of a ferment was not proved, because brain tissue would undergo autolysis in saline. The Wassermann reaction in the fluid might be positive in abscess of the brain and lead to an erroneous diagnosis of neuro-syphilis. Mr. D. L. SEWELL, Mr. SCOTT RIDOUT, and Mr. NORMAN BARNETT joined in the discussion. Mr. W. M. MOLLISON followed with a paper on the drug treatment of spasmodic rhinorrhoea. He described numerous remedies, but had found many cases relieved by the administration of calcium salts in conjunction with extract of parathyroid or of thyroid gland. Mr. SEWELL (Manchester), Dr. JAMES ADAM (Glasgow), and Mr. F. H. DIGGLE (Manchester) discussed this paper. The morning ended with papers by Mr. RITCHIE RODGER (Hull) and Mr. NORMAN BARNETT (Bath), which were a plea for the more efficient treatment of discharging ears and for the prevention of this malady.

Thursday, July 25th.

PERSISTENT NASAL CATARRH.

The proceedings opened with a paper by Dr. DAN MCKENZIE on persistent nasal catarrh, especially in children. The local causes of nasal catarrh in children, together with the means of dealing with them, were fully described, but there were cases which failed to respond, and for these a plea was made for a *via media* and the avoidance of extreme measures either of exposure or of coddling. Mr. F. B. GILHESPY (Birmingham) gave an account of an investigation of fifty children with nasal discharge who were kept under observation for two years. Thirty-two of these had infection of the maxillary antrum. The cases were fully analysed under four groups relating to the presence or absence of adenoids and of maxillary sinusitis. Attention was drawn to the failures after removal of adenoids due to sinusitis or ethmoiditis in children. It had to be remembered also that a purulent nasal discharge might be due to the Klebs-Loeffler bacillus. Dr. DOUGLAS GUTHRIE (Edinburgh) presented a careful review of this question, emphasizing that in those children where no apparent cause could be found there was usually nasal obstruction. Cleansing of the nose was important, and large doses of sodium bicarbonate were beneficial. The dental condition was important, but most important of all was restoration of the respiratory function by systematic re-education, and the breathing exercises must include proper expiration as well as inspiration. Mr. T. C. GRAVES (Birmingham Mental Hospitals) described cases of mental disorders due to this cause, and the discussion was continued by Dr. P. WATSON-WILLIAMS and Dr. NAISH (Sheffield), who insisted on the importance of sneezing.

Dr. GORDON WILSON (Chicago) then demonstrated a model of the endolymphatic valve, which lies between the saccus endolymphaticus and the utricle. Investigation had proved its existence in a variety of animals, but its function was so far chiefly a matter of surmise. It was presumably concerned in regulating the pressure of the fluid in the saccus endolymphaticus.

TUBERCULOSIS OF THE LARYNX.

The important business of the morning then followed, when the Section of Tuberculosis joined in a discussion on tuberculosis of the larynx. This was opened by Mr. W. G. HOWARTH, who gave a brief but comprehensive review of the whole subject, but referred chiefly to treatment. The chief means at present were absolute vocal rest and the galvano-cautery, which had now been substituted for any other active surgical treatment. Sunlight had been employed, but too much sunning might be harmful, whilst artificial sunlight, advocated by Wessely, only acted very slowly, and the treatment was lengthy. Tracheotomy was justified by obstruction, and for an occasional indolent lupoid infiltration, where the lung was inactive or fibroid. Nerve blocking for dysphagia had proved disappointing, and the application of cocaine to the spheno-palatine ganglion had only a transitory effect. Creosote in olive oil and chaulmoogra oil had been advocated also. The contribution of Sir STCLAIR THOMSON was mainly statistical, and he was able to show that complete repair of the larynx had been obtained in no less than 25 per cent. of patients with tuberculous laryngitis. That was encouraging to those who recalled that Morrel Mackenzie wrote that "it is not certain that any cases ever recover." Sir StClair Thomson showed many slides illustrating the appearances of the larynx in the various stages and during the process of repair. Mr. H. MORRISTON DAVIES (Vale of Clwyd Sanatorium) emphasized that a knowledge of the condition of the larynx was very necessary to the physician treating pulmonary tuberculosis, but even more so to the surgeon when the suitability of the case for operation had to be decided, and each case had to be considered from the vantage point of the lung and of the larynx separately. There were many laryngeal conditions which presented an absolute barrier to the operation of thoracoplasty in an otherwise suitable case. Such were malnutrition from pain on deglutition, extensive oedema or induration of the larynx, or such destruction of the glottis that the explosive power of the cough was lost. Tuberculous laryngitis was no contraindication in itself to artificial pneumothorax, but this proviso excluded these types of laryngeal tuberculosis. The state of the larynx had also to be taken into account when phrenic evulsion was under consideration. Sir J. DUNDAS-GRANT, Dr. SCOTT STEVENSON, Dr. MORITZ, and Dr. SUTHERLAND (President of the Tuberculosis Section) joined in the discussion.

In the afternoon Mr. Westmacott took members to a demonstration of instructional methods at the Royal Deaf Schools, Old Trafford, by Mr. J. Spalding. The children had been formed into corps of boy scouts and girl guides, and the training had been so perfect that they were able to respond to the word of command, and performed their exercises as smartly and efficiently as though they had good hearing.

SECTION OF OPHTHALMOLOGY.

Wednesday, July 24th.

TOXIC ABSORPTION DUE TO FOCAL SEPTIC LESIONS.

A DISCUSSION on toxic absorption due to focal septic lesions, with special reference to its effect on the production of eye disease, was introduced by Mr. A. F. MACCALLAN, who detailed the various sites of the septic foci. The more common were dental apical abscesses and tonsillar infections in children. Less frequently intestinal and appendix diseases were concerned, and, in women, affections of the pelvic organs. The various ocular diseases which were attributed to these causes were corneal ulcer, episcleritis, conjunctivitis, chalazion, iridocyclitis, phlyctenular conjunctivitis, dacryocystitis, retinal hyperaemia, vitreous opacities, primary glaucoma, cataract, and progressive myopia.

Dr. ARTHUR F. HURST (Windsor Forest) held the opinion that the mouth must be considered as a whole, and all dead teeth be regarded as possible sources of infection. Buried septic roots should be searched for in edentulous patients. He agreed that the tonsils and paranasal

sinuses were a frequent source of infection, but not duodenal ulcer. In Dr. Hurst's experience achlorhydria was a common cause of septic infection, and was due to the loss of bactericidal power of the gastric juice. Dr. ARNOLD RENSHAW (Manchester) thought that remote infection was a frequent cause of ocular inflammations. He classified such infection into four groups: (1) infection during septicaemia, (2) embolism in chronic sepsis, (3) reaction to toxins elaborated in another region, and (4) degenerative changes due to abnormal enzyme action. Mr. E. MUSGRAVE WOODMAN (Birmingham) said that the upper nasal sinuses were a frequent source of infection, not only in ocular but also in cerebral conditions. The method of washing out these areas was described and the results of such treatment in these cases were outlined. The great difficulty of carrying out this method of treatment was emphasized.

Mr. E. E. MADDOX (Bournemouth) confined his remarks to dental infections, and pointed out the close relation between the teeth and the eyes. He warned his hearers that because dental sepsis was present it was not necessarily the cause of an ocular condition, although it frequently was so. He quoted cases of detached retina which had been relieved by extraction of septic dental roots. He pointed out that in children the upper parts of the teeth and superficial areas in the eyes were associated, whereas in adults it was the deeper dental infection which was related to deeper ocular conditions such as choroiditis. Dr. INGLIS POLLOCK (Glasgow) emphasized the danger of infected unerupted teeth as a cause of ocular disease. He did not think retrobulbar neuritis was frequently due to paranasal sinusitis, and rarely found operation was called for in these cases.

Dr. P. WATSON-WILLIAMS (Bristol) drew attention to many cases of nasal sinusitis which caused ocular disease and distinguished between a bacterial and a toxin infection. The methods of tissue defence were described, and the advantage of eliminating the primary focus dwelt upon. Dr. E. J. PRIMROSE (Glasgow) described syphilitic ocular infections which were combined with septic infections, and insisted that both should be treated. Mr. ORMOND mentioned the septic origins of detached retina, and suggested that the ultimate cause might be a chemical one, secreted by the primary bacterial focus. He asked if dendritic keratitis was found to be benefited by dental treatment. Mr. LEASK cited fourteen cases of orbital cellulitis due to nasal sinusitis. Mr. T. ARMEY JONES (Stoke-on-Trent) thought that these ocular diseases were merely symptoms. He had treated these patients on the lines suggested by Mr. McDonagh. Dr. GRAVES discussed infection of the pituitary body due to sepsis and the treatment by non-specific protein therapy such as T.A.B. vaccine. He quoted the results of the treatment of residual abscesses found in antral inflammation. Mr. BISHOP HARMAN discussed the question of ocular conditions in children due to septic teeth and tonsils, and pointed out in which part of the cornea phlyctens began when caused in this way. He quoted cases of detached retina due to dental and nasal sinusitis. Mr. MACCALLAN, in reply, said he had known cases of dendritic ulcer clear up when dental sepsis had been relieved.

In the afternoon a clinical meeting was held at the Manchester Royal Eye Hospital, when cases were shown and specimens exhibited.

SECTION OF RADIOLOGY AND RADIO-THERAPEUTICS.

Wednesday, July 24th.

X-ray Diagnosis of Early Carcinoma of the Stomach.

DR. W. J. S. BYTHELL presided over this Section, and in a few opening remarks pointed out that, twenty-seven years ago, when the Association last met in Manchester, the subject of radiology was in such an embryonic state that no Section was allotted to it. Professor MARTIN HAUDEK of Vienna then read the paper on *x* rays in the diagnosis of early carcinoma of the stomach which is printed in full at page 173 of this issue.

Dr. A. E. BARCLAY (Cambridge) considered that the statistics given in the paper were of great value; indeed, the contribution was of the kind which should be kept handy, and consulted from time to time. He supported Professor Haudek's contention that one of the causes of failure was delay in making the examination. The latent factor was one which defied detection unless a routine examination were undertaken in the case of every apparently healthy person aged 40 and over. On one occasion the speaker had made a bad mistake while feeling very tired during the war; he pronounced a certain stomach to be normal, whereas it turned out to be the seat of an infiltrating scirrhus. When an observer felt very fatigued his judgement was liable to be disorganized. As for methods, he himself had not used the capsule; he employed a bolus of very thick food. The study of mucous membrane patterns was well worth while. A growth had the effect of cutting off the mucous membrane pattern, whereas in simple ulcer with cicatrization it was infolded. He was glad that the value of re-examination had been insisted on. Non-radiological colleagues sometimes expected an instant diagnosis to be made on a first glance at the radiograph, but an examination to be of any value took time, and no radiologist should be afraid of making a re-examination. If the radiologist was not well acquainted with the normal he would make many diagnostic errors. In early carcinoma a rapid emptying of the stomach was often to be noted—it did not seem to matter whether the growth was at the cardiac end or further down—and he would like to learn from Professor Haudek as to the reason. Dr. CECIL BELL said that in *x*-ray work, more than in any other branch of science, the workers were indebted to the pioneers, and especially in this field to Haudek for the standards laid down with regard to the motility of the stomach. When the signs of cancer of the stomach were yet slight, no method of elucidation was so valuable as *x* rays, and there could be little excuse for waiting or for making a mistake. Sometimes spasm of the stomach was helpful, and at other times the reverse; in a fat person, with a high stomach, it was very difficult to detect. Fluoroscopic visibility was notoriously bad. Spasm in the fundus and the greater curvature, which could not be palpated, was difficult to interpret. Fortunately cases rarely started in that situation. Dr. GILBERT SCOTT recalled the thrill he experienced when he first detected, by the Haudek method, an ulcer on the lesser curvature, which was verified at operation. The technique advocated was one which should be used in all routine examinations, not only for new growths, but for all kinds of lesions. He was keen on systematic radiographic palpation of the stomach, using a small meal at first, and "whitewashing" the interior of the stomach, visualizing the rugae, in preference to filling up the stomach and examining it by silhouette. When the lesion was a simple one the rugae tapered off gradually, but when the filling defect was due to malignant disease they stopped abruptly. The meals given should be so thick that a portion adhered to the ulcer surface; with a watery solution this did not happen. It was well to try the consistency on the cadaver. With regard to history, it was best to go into this after attempting to interpret the radiographic findings. Generally, the less one was guided by history the better. He had also come to disregard indirect evidences, such as tender spots or muscular rigidity. Having detected a lesion, how far was the radiologist justified in giving an opinion, as to its nature? In borderline cases it was difficult to distinguish between a large benign chronic and a chronic upon which a malignant section had become engrafted. On radiographic examination alone the point of malignancy should not be determined. Radiologists should keep in touch with the operative findings; thereby their diagnostic skill was prevented from becoming stationary. The radiologist should not venture an opinion as to whether a case was operable or not, as surgery accomplished many things now which would not have been thought possible a short time ago. He hoped the paper would act as a stimulus to radiologists to bring their methods up to date. Reliance must not be placed on indirect evidence; it was necessary actually to see the culpable lesion, especially as there existed so many fallacies and pitfalls. He wished to know whether peristalsis reaching to the point of defect in the

outline was of value in distinguishing between simple adenoma and malignant tumour. Dr. L. A. Rowden (Leeds) was pleased to hear Professor Haudek advocate deliberate and unhurried examination of *x*-ray plates. The speaker always took a good time over this, often half an hour. He also insisted on examining the patient in the prone position. It was a great aid to watch the peristalsis on the lesser curvature if the tube was brought up close beneath the patient; it resulted in a greater exaggeration of the peristaltic wave. Help was also obtained from serial radiography of the pyloric end—he meant, taking radiograms at intervals of a minute. He believed that the number of people now being operated on in the way of stomach resection for malignant disease was on the increase; formerly it was a case of doing a laparotomy and closing up. He believed that in a person of a certain age, with obvious pyloric obstruction, if the stomach was small, the obstruction was due to malignant disease; if large, it was *not a malignant* case.

The President (Dr. Bythell) spoke of two recent cases in which the screen and film examinations strongly suggested malignant disease of the pylorus, but operation showed there was a small malignant growth in the head of the pancreas, yet producing a filling defect. These cases were difficult to distinguish from those in which the cancer was actually in the stomach wall. He did not agree with Dr. Scott's excessive caution before diagnosing malignant disease; he had long felt that the opaque meal and *x* rays afforded better means of recognizing this disease than any other. With improving technique and closer observation this would probably become more and more the case. Professor Haudek, in reply, said that twenty years ago patients had their second examination twenty-four hours after the first, but he had long since concluded that the interval was too great. Six- and four-hourly intervals were his present practice. Some stomachs not the seat of lesions emptied rapidly, and in general he asked for caution before making a diagnosis on functional symptoms. Sometimes the jejunum took on the functions of the stomach. A tumour outside the stomach always caused diagnostic difficulties. Usually he examined a patient first before taking any notice of the history. In all cases it was important to remember that the *x*-ray examination was no more than a partial diagnosis. In conclusion, Dr. Haudek spoke of his great admiration for British science and culture.

SECTION OF VENEREAL DISEASES.

Wednesday, July 24th.

Lesions of Latent Syphilis.

The President of the Section, Mr. William Coates, took the chair at the opening meeting, which dealt with the above subject. In the course of a presidential address, he referred to the fact that the present was the fourth occasion on which there had been a Venereal Diseases Section at the Annual Meeting. Co-operation between all branches of the profession was needed to wage war against the group of venereal diseases. The policy of the Ministry of Health was a wise and far-reaching one, based upon achieving the ultimate welfare of the nation. Much remained to be done in the way of research, and agents must be found whereby immunity might be ensured. The discussion was opened by Professor Aldred Scott Warthin (Michigan), who illustrated his theme by a series of original and valuable photomicrographs. He said that the lesion of latent syphilis was pathologically a repetition of the hard chancre and of the secondary and tertiary lesions of the active stage of syphilis, by reason of the fact that it was principally vascular and perivascular, and that the infiltrations were produced by the proliferation of the cells *in situ*. If plasma cells and lymphocytes were found forming local perivascular infiltrations, this fact might be taken as evidence of the presence of *Spirochaeta pallida*. Clinical symptoms did not arise until the resultant atrophy and fibrosis of the parenchyma produced functional disturbances. In the male, functional inadequacy generally first affected the cardio-vascular system, and therefore accounted for the frequency of deaths from cardiac insufficiency in patients with latent syphilis. Dr. Warthin had never seen at a necropsy a case of perfectly healed syphilis. It was important to realize that the foregoing statement applied to patients subjected either to mercurial or to the more modern methods of treatment, the difference being that chronic hepatitis followed more frequently upon the treatment by modern methods. Either form of treatment achieved a more rapid reduction of the average active case to a stage of latency. There was no evidence pathologically that a case of syphilis ever became entirely free from spirochaetes. Latency of infection might persist through life, or exacerbation take place at any time. The determining factor of this resuscitation of spirochaetal virulence was not known, but the possibility of its occurrence hung over the head of every infected individual. The relatively immune syphilitic patient might go through life free from any clinical outbreak, yet by the development of various functional abnormalities he paid the price of the latency of the infection. The very mechanism of immunity became in time a source of danger to its possessor by reason of *the functional inadequacies produced. If antisyphilitic* treatment was carried out consistently for five years, would spirochaetes entirely disappear from the body? To this all-important question Dr. Warthin could give no answer. Sir Humphry Rolleston, after expressing admiration for Professor Warthin's valuable paper on a subject on which he had long been the authority, said that this work confirmed the dictum of Sir William Gull fifty years ago, "Call no man cured of syphilis until my friend Wilks has done his post-mortem." But was it to be concluded that syphilis was absolutely incurable when early and efficient treatment was employed? The occurrence of second infections was generally regarded as evidence that the first infection had been entirely removed. Halley and Wasserman of Baltimore,[1] who accepted 237 only out of 684 reported cases of second infection with syphilis since 1910, showed that the number of cases of second infection diminished as the interval between the onset of infection and the commencement of treatment increased, for out of these 237 cases 232, or 97.8 per cent., were treated during the primary or secondary infection. They also found that the ratio of patients treated in the early and late stages respectively was as one to two, and yet secondary infections occurred forty-six times more often in the early than the late series of cases treated. This would suggest that early treatment might prevent the haemic infection from producing the lesions of latent syphilis, so carefully described by Professor Warthin in the dead body, but that tertiary syphilis was curable. In support of this deduction was Halley and Wasserman's statement that they did not find *any undoubted* case of second infection in a patient who had, previously or concomitantly, had syphilis of the central nervous system or of the heart or aorta. A point of great clinical importance, the relation of latent syphilis to the Wassermann reaction, had not been considered by Professor Warthin. Cases occurred of tertiary syphilis—especially of the liver—which presented clinical manifestations, and so were far from latent, yet in which, as had been emphasized by McCrae and Caven,[2] the Wassermann reaction was negative. In such clinical cases the therapeutic test was of value.

Dr. H. M. Hanschell said that careful clinical observation gave no support to the thesis that there was noticeable early loss of sexual desire and potency in man after infection with syphilis. The clinician would anxiously ask whether Professor Warthin included serological cures—that is, Wassermann-negative blood serum—in the "complete clinical cure" of his necropsy material. Proof, however, of complete cure in the sense of complete disinfestation must ultimately rest on research such as Professor Warthin's. Professor Warthin had shown that each localization of spirochaetes led to a chancre. Conclusions drawn from observations on the penile chancre were then valid for the localized chancres in other organs lying beyond observation in life. Dr. Hanschell cited cases where treatment had failed to destroy all spirochaetes in the primary lesion, or to prevent clinical or serological relapse so long as some palpable, though slight, induration

[1] Halley, C. R. L., and Wasserman, H. *Arch. Int. Med.*, Chicago, 1928, xli, 843.
[2] McCrae, T., and Caven, W. R.: *Journ. Amer. Med Assoc.*, Philadelphia, 1925, clxxii, 781.

remained at the site of the primary penile lesion; and in which, after extirpation of that residual induration (granuloma), the same treatment as before had been followed by absence of clinical signs of syphilis, and by a Wassermann-negative blood serum and cerebro-spinal fluid, for periods of observation of the patients ranging from two to five years. He concluded that the dense persisting granuloma on the penis had shielded its contained spirochaetes from the drug. If this were true of the granuloma on the penis it was true of the granuloma in any other part of the body. In face of this comparative impenetrability of the granuloma it was unnecessary to postulate the existence of drug-fast spirochaetes, intracellular spirochaetes, or spirochaete granules, to account for latency and failure of treatment.

Dr. NABARRO, in dealing especially with latent congenital syphilis, emphasized the need for the employment of more thorough methods of investigation in certain cases —for example, a confirmatory Kahn, Sachs-Georgi, or Vermes test, as well as the Wassermann test, with regard to mother and child. He referred especially to cases of mild hydrocephalus, mental backwardness or deterioration, swelling of joints, adenitis, spastic and other paralysis. Early diagnosis and prompt treatment might prevent tragic catastrophes. The spinal fluid should be examined in every case of congenital syphilis. X rays should be used in diagnosing congenital syphilis, as very many infants were thus found to show a characteristic osteochondritis, osteitis, or periostitis. The speaker illustrated his statement by lantern slides. As in acquired syphilis, so in congenital, the heart, vascular, and endocrine systems might be invaded by spirochaetes. Dr. Nabarro announced his intention of employing in the future the Warthin-Starry method of demonstrating spirochaetes. In conclusion, he made an earnest appeal on behalf of the congenital syphilitic. Colonel E. T. BURKE (Manchester) said the term "endosyphilis" was more desirable than "latent syphilis." It was necessary to destroy the idea that the condition under discussion might be "inactive." He wished to know what proportion of Professor Warthin's post-mortem material showing histological evidence of active syphilis was negative to serological tests during life. He made a strong protest against the "standard" treatment of syphilitic patients without reference to the disease itself and its true pathology. In this way were "endosyphilitics" made. In applying serological tests of cure to treated patients it was necessary that the patient should have had a provocative injection and have been subjected for weeks to large doses of iodides, in order to break down his fibrous tissue fortification. He believed that endosyphilis was one of the commonest affections of a modern community. Colonel L. W. HARRISON wished to strike a more optimistic note than Professor Warthin's. He had difficulty in believing that treatment with novarsenobillon was productive of immunity only; why otherwise did spirachaetes disappear to the extent shown by experiment? He believed N.A.B. to be of distinct benefit in cardio-vascular cases of syphilitic origin. Mr. LEES (Edinburgh) wished to know why the ovary and Fallopian tubes failed to show the presence of spirochaetes, and also whether the organisms were alive in cases of latent syphilis. Professor LORAIN asked what was responsible for causing "atrophy" of the liver in cases of syphilis. Professor Warthin regarded the condition as being due to a vascular factor, and not to spirochaetal toxins. Dr. HENRY GLUCKMAN (Johannesburg) asked if Professor Warthin's statement that he "had never seen a perfectly healed or completely cured syphilitic" applied even to the earliest primary type of case—to the patient whose only manifestation was the primary lesion, and who had been treated by modern methods from the very start. He further inquired as to what attitude was to be adopted towards a patient who, many years previously, had had syphilis, for which he had been intensively treated, and wished to get married. He had no symptoms, but the Wassermann reaction was positive. Should he be treated intensively, and should he be allowed to marry? Unfortunately, course after course of treatment might have little effect on the serological picture, while clinically such a patient frequently developed active lesions after treatment had been given.

Professor WARTHIN, in reply, was very doubtful whether any man who had suffered from syphilis should be allowed to marry. In replying to other questions and criticisms he stated that: (1) He was sceptical about so-called double infections with syphilis; animal experiments showed that "superinfection" with a spirochaete of a different strain might take place. In man, if this happened, he believed that there was no real cure of the first infection; the patient was not immune to the latent effects of the original strain of organism. (2) Clinical cure meant a high-grade immunity. (3) He believed in the use of "arsenicals," as thereby immunity was increased, though the liver was more injured. (4) He had found the histological lesions, on the whole, to be the same, whether cases had been treated well or indifferently or not at all. (5) He was definitely against arsenical treatment in cardiac cases. (6) He regarded the spirochaetes found by him in the cardiac and other lesions to be alive, or to have only recently died.

SECTION OF ORTHOPAEDICS.

Wednesday, July 24th.

OPERATIVE TREATMENT IN TUBERCULOSIS OF THE LARGER JOINTS.

SIR ROBERT JONES, the President of this Section, presided over its first meeting on July 24th, when Mr. C. R. GIRDLESTONE (Oxford) opened a discussion on the indications for, and the results of, operative treatment in tuberculosis of the larger joints, with a brief review of the pathology of joint tuberculosis. He brought forward a number of arguments in support of the opinion that the danger of dissemination of tuberculosis lay in the lymphatic lesions rather than in the joint focus. In both types of lesion the fundamental need of the patient was prolonged rest and fresh air treatment. The part the surgeon could play in the treatment of tuberculous joints was: (1) to remove a tuberculous focus, metastatic in origin, and a potent source of toxaemia; (2) to buttress or rebuild a part of the skeleton which could not otherwise safely carry the strains it would have to bear. He operated at a time so chosen as: (1) to interfere least with the improvement of his patient's vitality—indeed, in some middle-aged or old patients radical measures were necessary in order to make that improvement possible; (2) to supply him with materials which would answer his needs (this applied to buttress building). Radical operations might have to be performed comparatively early, to save life and limb in the middle-aged or old; extra-articular arthrodesis was best done later. He next discussed the indications for, and results of, operation in the individual joints, ending with the method of drainage employed when secondary infection had taken place. For adults aspiration of the joint lesion should be performed whenever possible, supplemented by graft extra-articular fixation in the case of the hip-joint. In sacro-iliac disease an extra-articular arthrodesis alone was recommended. As regards children, Mr. Girdlestone felt that both the hip- and the knee-joints required operative fixation more frequently than had hitherto been generally accepted. He emphasized the point that in such cases an operation was only valuable if it was an integral part of a long course of general treatment, in the open air. Apart from such treatment these operations were useless.

Sir WILLIAM DE COURCY WHEELER (Dublin) said he would refer to some points in diagnosis, to the work of the older surgeons, and to some lessons learned from personal experience. He was not convinced that the fate of a patient suffering from bone and joint tuberculosis depended entirely on the showers of bacilli from the primary focus with which the patient was drenched. After effective operation, either fixation or amputation, the patient was cured, as well as the local condition. Each joint was a problem in itself, and treatment needed modification according to the facilities at hand. The diagnosis was often difficult, because, he believed, a mixed infection was frequently carried from the primary focus; at various stages one organism predominated and the other was submerged. Thus cases occurred of clinical osteomyelitis which were microscopically tuberculous, and many cases with osteoblastic

activity in which tubercle bacilli were found. Mixed local infections confused the diagnostic issue. Some cases of tuberculosis were definitely associated with general streptococcal infections. Tubercle bacilli were regularly found in tuberculous pus and in the urine in a number of cases of bone and joint tuberculosis. Sir W. Wheeler advocated free and frank excision of the knee in adults with retention of the patella. He was not sure that complete removal of the synovial membrane was necessary; if it was, the arguments in favour of extra-articular fixation of the hip fell largely to the ground. If children needed operation, arthrodesis, with a very limited removal of bone, gave good results. He discussed arthroplasty, which had a limited field of usefulness, and mentioned a case, published by Bennett in 1886, in which, more by accident than design, an excellently functionating movable joint was obtained after free excision for tuberculosis. It was just possible in carefully selected cases that a movable joint might be aimed at and obtained when treated on the same lines as excision of the elbow. Early osteotomy of the femur in the active stages of tuberculosis of the hip was sometimes followed by rapid repair of the joint. The leverage of the limb was removed for the time being, and osteoblastic action extending upwards from the fracture appeared to help. He showed lantern slides illustrating the results of removal of the head, neck, trochanters, and part of the shaft, together with the results of astragalectomy in children, and of excision of the elbow, wrist, and other joints. He looked upon extra-articular arthrodesis of the hip as a formidable procedure in delicate children, but he had only a limited experience. He was surprised to find the end-results of sacro-iliac disease in his own cases as good as they were. It was the part of the surgeon to keep an ever open mind; the pendulum of the surgical clock moved erratically, and history taught that the hands of the surgical clock often moved backwards instead of forwards. The speaker advocated conservative treatment if operations were needed, as they usually were in adults. Conservative treatment was a good pre-operative preparation, and was essential as a post-operative precaution against relapse.

Mr. A. MITCHELL (Aberdeen) emphasized the difficulty of establishing a diagnosis in tuberculous lesions, and of observing the patients over a period sufficiently long to allow conclusions of real value to be made. He laid stress upon the need of rest and exposure to the sun and air in all cases, but he was dissatisfied with the results of purely conservative treatment in a large proportion of the more advanced and serious cases. For that reason he recommended operative intervention at a stage earlier than that at the present time usually accepted as suitable. He advised waiting only until the acute and difficult phase had passed and the general health of the patient had improved.

Miss FORRESTER-BROWN (Bath) showed the desirability, when performing an extra-articular hip arthrodesis, of using a femoral graft with a surface sufficiently massive to make effective contact with the ilium, and described the operation which she used in suitably selected cases. In this, important features were the excavation of a deep bed in the overhanging lip of the acetabulum, and effective rawing of the femoral neck.

Mr. FAIRBANK protested against the practice of performing arthrodesis in adult tuberculosis of the knee. Removal of the whole disease should be the aim of the surgeon. When this was not practicable a true extra-articular arthrodesis should be done. He reminded the meeting of the old and effective use of sulphur by Sir A. Lane many years ago. Mr. HOWELL pointed out that sinuses may in exceptional conditions continue for years without serious menace to life. In children's knees his practice was to try conservative treatment for twelve months, and then, in suitable cases, perform an arthrodesis, using bipp. He deprecated the use of a tourniquet. Mr. A. W. ADAMS (Bristol) asked how often, in actual experience, did general tuberculous dissemination follow operative intervention. In children he recommended the removal, immediately on diagnosis, of foci situated in epiphyses or metaphyses. Early treatment would prevent secondary infection of the joint and would preserve function. Mr. W. R. BRISTOW questioned the reliability of the guinea-pig test for tuberculosis. Though a positive result was of great value, entire reliance was not to be placed on a negative one. He emphasized the difficulty of treating the tuberculous knee in the child, and recommended early arthrodesis when the *x* ray left no doubt that the function of the knee was permanently impaired. Mr. GIBSON (Winnipeg) had been much impressed by Hibbs's cases. He did not consider that without external assistance cases treated conservatively were capable of withstanding the strain of vigorous daily life. Arthrodesis combined with curettage was, in his opinion, the method of choice in treating knees.

Sir ROBERT JONES (Liverpool), speaking from the chair, deprecated any suggestion that there should be separate and distinct schools of treatment of joint tuberculosis. He had always regarded rest and fresh air as essential to success, but it was homage, and not allegiance, that he paid to any method of treatment. Any sound advance, such as Hibbs's operation, should be heralded with joy, but we must not forget that to give its best results each method must be supported by the application of the cardinal rules of rest in proper position and fresh air.

Demonstrations of cases were given in the afternoon at the Grangethorpe Ministry of Pensions Hospital by Mr. OLLERENSHAW, Mr. POSTON, Miss GREG, Miss JOHNSTONE, and Mr. PLATT. Dr. S. POPE reported the results of experimental production of brachial plexus lesions in the full-time foetus.

SECTION OF TUBERCULOSIS.

Wednesday, July 24th.

APICAL AND SUBAPICAL TUBERCULOSIS.

AT the opening of the Tuberculosis Section Dr. D. P. SUTHERLAND, the President, described briefly the origin of institutional treatment of tuberculosis in Manchester. He then introduced Dr. MAURICE FISHBERG, consulting physician to the Bedford Hills Sanatorium, New York, who opened a discussion on apical and subapical tuberculosis. After acknowledging the claims of Dr. William Ewart and Sir James Kingston Fowler in recognizing that early consolidations of the lung were more commonly situated in the subclavicular region than at the apex, and that the spread of the disease was possibly more rapid when the primary lesion occupied the former site, Dr. Fishberg drew a sharp distinction in the progress of the disease in these respective seats of origin. In his opinion patients with apical disease lived indefinitely unless carried off by some intercurrent disease. They were diagnosed as tuberculous by over-cautious physicians, and they supplied the clinical material for any "cure" which happened to be introduced. They supplied the "early" and "curable" cases considered ideally suitable for sanatorium treatment; they formed the large contingent of "repeaters" at sanatoriums and the droves of well-to-do tuberculous at health resorts, and they were the backbone of favourable sanatorium statistics. Apparently the lesions were the residua of childhood infection which had become obsolete, and had been discovered when, for some reason, a physical examination of the chest had been made. Subapical tuberculosis was a different matter. It more often occurred in individuals under the age of 25, who felt "out of sorts"; it had a relatively abrupt onset; and physical examination of the chest very often revealed nothing definite. Unless a good radiogram was taken, or tubercle bacilli were found in the sputum, the patient was apt to be treated for neurasthenia, bronchitis, or gastritis. Dr. Fishberg was of opinion that these cases were not of recent exogenous superinfection, and that in the vast majority evidence could be found of earlier tuberculous infection. In these subclavicular cases the lesion tended to extend, to caseate, to form cavities, and to lead to the common variety of chronic phthisis, with a prognosis much less favourable than in apical cases. From the therapeutic point of view the differentiation of apical from subapical lesions was of immense importance. Prophylaxis, in Dr. Fishberg's opinion, was mainly to be confined to the subapical group. Open tuberculosis was uncommon in the apical group; and as prophylaxis was one of the main reasons for institutional treatment, such prolonged and costly treatment was unnecessary in the vast

majority of apical cases. A large proportion of such patients could be discharged from sanatoriums with benefit to themselves, the institutions, and the committees charged with their care.

Sir HUMPHRY ROLLESTON said that the wide recognition of the primary focus of pulmonary tuberculosis had been emphasized by Sir Clifford Allbutt's paper at the Portsmouth meeting of the British Medical Association in 1899, when photographs were shown of Birch-Hirschfeld's fusible metal casts of the bronchi. Sir Humphry called attention to the loose use of the word "apex" in this country, when the expression "upper lobe" would be more correct. He expressed interest in Dr. Fishberg's argument in favour of an endogenous infection from dormant foci as opposed to *exogenous reinfection in a person who had lost all the immunity conferred by an infantile infection*; he doubted whether the question of the futility of retaining benign apical cases in sanatoriums bulked as largely here as it appeared to do in America.

Professor A. RAMSBOTTOM (Manchester) believed that the majority of true apical lesions originated in childhood as blood-borne infections, probably bovine. Their characteristics, if lighted up later, were chronicity and easy response to treatment. Adult tuberculosis began in the region of the hilum, or in the lower part of the upper lobe, or in the middle lobe. Professor Ramsbottom called attention to the difference in resonance, sometimes very marked, found in percussion of the upper lobes of opposite sides. He regarded abortive tuberculosis as a pathological fact rather than as a clinical disease.

Dr. JAMES WATT (King George V Sanatorium, Godalming) produced figures which he thought contradicted the idea that the infraclavicular lesion was of different type and prognosis from apical tuberculosis. He was sure that in many patients with apical infiltration the morbid condition went on to progressive phthisis, while many cases of infraclavicular lesions were benign. He based his conclusions on a search of 250 radiograms for the two types of the disease. In 32 cases which appeared to be apical, and 43 infraclavicular, the differences in history and clinical course appeared to be slight. Of the patients with apical lesions 58 per cent. left the institution with quiescent disease; of the infraclavicular, 48 per cent. He regarded it as a dangerous doctrine to suggest that the 32 patients scarcely required sanatorium treatment. He saw no reason why an infraclavicular focus should not arise sometimes from endogenous infection from a small apical lesion. He thought that the advocates of the newer views went much too far in saying that the infraclavicular site was almost invariably the origin of a spreading phthisis, while the apical site was seldom or never so. Morbid anatomists were almost unanimously opposed to this view. All the new work was based on radiography, which was not yet an infallible means of recognizing early tubercle. Dr. Watts was sure that apical tuberculosis was not diagnosed in this country with anything like the frequency it appeared to be in America and in Germany. His figures of T.B. positive cases was 72 per cent., as compared with Dr. Fishberg's 15. British sanatoriums could not, therefore, be accused of needlessly retaining obsolete apical cases. He was convinced that the so-called infraclavicular early infiltration was not something *sui generis*, but differed only in degree from the apical form.

Dr. W. BROCKBANK (Manchester) departed somewhat from relevance to the discussion by pleading for investigation of the influence of calcium in the repair of tuberculous lesions. He pointed out that only in tuberculosis, and some cases of pneumonoconiosis, did Nature attempt to combat the disease by the deposition of calcium salts. Moreover, pulmonary tuberculosis was almost unknown amongst workers in lime. The absorption of calcium from the alimentary canal was slow; but, administered intravenously, it raised the serum calcium above the normal for forty-eight hours. Injections were given to six patients suffering from fairly severe forms of phthisis. In four cases surprising improvement took place, and two of the patients maintained the improvement after the injections ceased. Two patients had relapses shortly after cessation of the treatment, but regained the ground when the injections were recommenced. Of the remaining patients one had improved gradually and steadily, while the other had been a failure. Dr. FISHBERG, in reply, suggested that radiography was not being used in Europe in the extensive manner now common in America. In this way many cases of the disease in America were discovered accidentally. Under similar conditions Dr. Watts's figures would have presented a different aspect.

SANOCRYSIN TREATMENT.

During the discussion on sanocrysin treatment of *pulmonary tuberculosis*, *Dr. J. R. GILLESPIE, Vice-President*, took the chair. Dr. R. R. CLARKE (Belfast) set himself four questions: (1) What were the dangers of sanocrysin treatment? (2) What was the correct dosage? (3) Had it any value in the treatment of phthisis? (4) What type of case did it benefit? It would appear, he thought, that sanocrysin was not injurious to healthy mammals in doses of 1 to 1.5 cg. per kilo of body weight; that tolerance was increased by graduated dosage at sufficient intervals; that the kidneys were mainly responsible for elimination; that the drug was much more likely to damage the tuberculous organism than the healthy one. Apparently the original dosage was excessive, and led in many cases to hyperpyrexia, intense focal reaction in the lungs, haematuria, albuminuria, anuria, jaundice, and sometimes death. By graduating the doses tolerance was created, and ultimately large doses were injected without causing any severe symptoms. Under such conditions Dr. Clarke had observed benefit in a high proportion of patients. Tubercle bacilli disappeared from the sputum; often the *x*-ray picture rapidly cleared up. Sometimes a shrunken fibroid lung was observed. The phthisical facies disappeared. Among the exudative group of patients there was heavy mortality, but many did well. In the fibroid group the results were more satisfactory. Dr. Clarke thought that with unilateral disease, and when collapse therapy was clearly indicated, sanocrysin should not be used unless, later, fresh foci developed in the functioning lung. But the drug was a valuable aid to treatment if used with caution. Dr. F. HEAP (Warwickshire) had treated 120 cases at the Warwickshire Sanatorium with small and gradually increased doses of sanocrysin, varied according to weight and sedimentation rate. He had found that the cases had a rather better prognosis than otherwise, and that benign cases benefited more than the malignant. The immediate results in the way of arrest were good, the symptoms disappearing in many cases, and the sputum being negative in five examinations. But in fifty cases of artificial pneumothorax, as similar as possible to cases treated with sanocrysin, the results from the former procedure were decidedly superior. In ten children treated with the drug the results were encouraging, especially considering the unfavourable nature of the prognosis in children with positive sputum. Dr. P. W. EDWARDS (Market Drayton) had treated with sanocrysin thirty-seven patients with very advanced exudative phthisis. Of these, thirty-one were definitely improved, three became worse, and three died. Sputum ceased in fifteen cases, and bacilli disappeared in twenty-four. The results appeared infinitely better than in cases not treated by sanocrysin, but so far the patients had not been followed up. Rashes in the course of treatment should not be overlooked, as their cure was frequently a prolonged matter.

Dr. W. STONE (Oxford) thought that complications due to sanocrysin might perhaps be avoided by diluting the fluid medium, or possibly by using normal saline as a diluent. The use of glucose also might be useful. He was inclined to use the treatment in some moderate fibrocaseous cases, though these should be treated mainly with tuberculin. Patients treated with sanocrysin could be got out of the sanatorium in three months instead of twelve. Professor S. LYLE CUMMINS (Cardiff) submitted a paper, which was read by Dr. Dobson. He deprecated comparison of sanocrysin treatment with such methods as artificial pneumothorax or sanatorium treatment. Sanocrysin represented a direct attack on the causative agent or the infected foeus. He gave a detailed account of twenty-one cases treated with sanocrysin between 1925 and 1928, and followed up. Six of these, probably seven, were known to be dead. Three patients could be regarded as well; five were decidedly

better, one was *in statu quo*, and four were worse. But in every suitable case marked improvement had followed the treatment temporarily. Professor Cummins therefore advocated sanocrysin for raising the status of certain patients so that they might enjoy the benefits of collapse therapy or sanatorium treatment. Dr. J. R. GILLESPIE (Manchester) hoped that the discussion would throw light on the dosage question, which still seemed to be in an experimental stage. It seemed possible that doses should be given, as with tuberculin, in geometrical rather than arithmetical progression. Dr. CANTOR (Manchester) described the use in Paris of the double thiosulphate of gold and sodium, known as crisalline. Patients with moderate temperatures responded best to the treatment, with diminution of fever, cough, sputum, and number of bacilli. Radiographic signs cleared up remarkably. The results in afebrile cases were not so marked as in the moderately febrile. Dr. CLARKE, in reply, said he was glad that so much interest was now being taken in sanocrysin in this country. He thought that a closer study of individual cases was necessary.

SECTION OF PUBLIC HEALTH.

Wednesday, July 24th.

REDUCTION OF HUMAN TUBERCULOSIS OF BOVINE ORIGIN.

DR. W. G. SAVAGE (Somerset), in his opening paper, gave a number of figures which he contended proved that the death rate from tuberculosis of bovine origin was steadily declining, and that its prevalence was often exaggerated. As to the extent of bovine tuberculosis, he said it varied in different areas, but probably 40 per cent. of all cows were affected. Most of these were non-infectious and never became infectious. He estimated the number of actually infectious animals as probably less than 1 per cent., and the number of cases of disease of the udder as 0.3 per cent. as a maximum, and in some areas considerably less. Dealing with preventive measures he regarded the elimination of all tuberculous animals as impracticable. The attempt to build up tubercle-free herds had not been successful, but had had considerable educational value. Routine veterinary inspection would remove cases of gross infection, but could not remove all sources of infection. He advocated improvement in the hygienic environment of the cows, and even the abolition of the cowshed. In the meantime pasteurization of the milk supply was probably our best safeguard against infection. Colonel BRITTLEBANK (Manchester) expressed disappointment at Dr. Savage's rather pessimistic attitude, and challenged his figures. He believed that Dr. Savage had underestimated the prevalence of the disease, and contended that routine veterinary inspection had already achieved a proved success.

Mr. A. GOFTON (Edinburgh) also challenged Dr. Savage's figures and quoted others from reports of the Board of Agriculture which contradicted them. In his experience every reacting cow was capable of becoming a source of infection. Dr. MORISON (Cumberland) said he believed at least 5 per cent. of all cattle had definite infections and 25 to 30 per cent. were reactors and capable of infecting the milk they produced. He believed the safest and best form of milk for distribution was dried milk. Dr. EUSTACE HILL (Durham) also expressed his disappointment at Dr. Savage's pessimistic attitude. He himself was more optimistic. In his experience 10 per cent. of all samples of milk were found to be infected. In Durham, as in the West Riding of Yorkshire, routine veterinary inspection was carried out by a full-time staff and was resulting in a definite improvement. Sir MALCOLM WATSON (Malaya) said that in that country there was no tuberculosis among the cattle, and surgical tuberculosis among children was unknown. He attributed this to the fact that the cattle were not kept in cowsheds. Dr. MIDDLETON MARTIN (Gloucestershire) emphasized the difficulty of diagnosis, and also advocated the value of pasteurization as a safeguard. Dr. SAVAGE, in reply, maintained the accuracy of his figures, and stated that those quoted by Mr. Gofton referred to selected groups and not to the cow population as a whole.

RIVER POLLUTION.

In the absence of Dr. McLEAN WILSON (West Riding River Board) his paper on river pollution was read by Dr. Calvert. It opened with a brief description of the terrible conditions which prevailed some forty years ago, in spite of the reports of the Royal Commissions of 1865 and 1868. Only spasmodic action was taken, although the Thames Conservancy Board was already an active body, being charged with the duty of protecting the London water supply. The passing of the Public Health Act of 1875, and the Rivers Pollution Prevention Act of 1876 indicated that the public conscience was becoming stirred by the foul condition of the rivers generally. It was not until the formation of the county councils and county borough councils in 1889 that any serious work was done, and then only by a minority of the counties. Later on fresh parliamentary powers were obtained by the Mersey and Irwell Joint Board and the West Riding Rivers Board. After considering the comparative inaction of the local authorities up to the present he asked, What was the remedy? He believed it was to be found in the report of the Royal Commission of 1898, which strongly advised the formation of joint committees or boards to deal with rivers throughout their whole length. Without such boards he did not think the proper measures were likely to be thoroughly undertaken. Dr. W. G. SAVAGE dissented strongly from the proposition that rivers boards should be set up everywhere. While they might be necessary in heavily industrialized districts, in more rural areas the county council was the proper body to administer the existing powers. What was needed was amendment of the law. A very serious problem was the occasional discharge of works refuse of a highly polluting description. The best standard to be aimed at in country districts was a degree of purity which would not be injurious to fish life. Mr. H. STOWELL, M.Inst.C.E. (Manchester), said that he believed joint boards were the best means of co-ordinating the activities of local authorities. Industry was spreading southwards, and we were faced with problems connected with trade waste from new industries, especially the manufacture of artificial silk and beet sugar. The need for amendment of the law was urgent. There were too many Acts, and procedure was too cumbrous. The Act of 1876 was riddled with inconsistencies. What was needed was a consolidating Act on the lines of the Salmon and Freshwater Fisheries Act, with clauses on the lines of those obtained under several private Acts. A paper by Dr. MEREDITH YOUNG (Cheshire) was read in his absence by Dr. Tough, dealing mainly with the purification of tidal rivers and estuaries. Dr. EUSTACE HILL (Durham) agreed with Dr. Savage that the establishment of numerous joint boards would be undesirable. The matter was a national one; it should be dealt with on a national scale by a centralized department. Dr. MIDDLETON MARTIN (Gloucestershire) said he would not be jealous of any other body that could do the work better, and mentioned the admirable work done by the Thames Conservancy Commissioners. He regretted that the condition of the Severn compared unfavourably with that of the Thames. Dr. CALVERT replied briefly on the points raised. In closing the meeting, the President, Dr. VEITCH CLARK, proposed a vote of thanks to the speakers, which was carried with acclamation.

SECTION OF OCCUPATIONAL DISEASES.

Wednesday, July 24th.

OCCUPATIONAL DUST.

AT the first meeting of the Section Dr. DEARDEN, the President, gave a cordial welcome to all present, and referred to the fact that the Section was first held in 1902 in Manchester, on the occasion of the centenary of factory legislation and regulation.

Dr. J. C. BRIDGE, H.M. senior medical inspector of factories, introduced the subject of occupational dust. He said that it was common in such papers to deal with mortality rates, but he would submit that these did not give a complete picture. Dr. Dearden, in his Milroy

Lectures, had added the subject of occupational sickness, and that and the habits of the worker added much to a complete presentation of the subject. After defining dust and classifying dusts as toxic and non-toxic, he proceeded to speak briefly on some of these—for example, lead, silica, aniline products, organic dusts, wool, cotton, moulds—and pleaded for a new nomenclature in the group of dust diseases. He referred briefly to the incidence of cancer of the lung, skin, and bladder, and alluded to the peculiarity of the industrial dermatoses which, though mostly local, could and did affect the skin generally. He concluded by emphasizing the need for co-operation between the engineer, chemist, and industrial physician in the solution of the problems of occupational dust. Dr. W. E. COOKE (Wigan) said that asbestos belonged to the pyroxene group of minerals, and was mostly silica in chemical composition. Black particles containing iron varied in frequency. The fine black granule dust in the carding room contained 18 per cent. of iron oxide. Necrotic areas in the lung showed similar large black and blue-black fragments. In addition to these large black bodies and fine granules, curious streptococcal, dumbbell, as well as many nondescript forms were seen in lung sections. They were 100 to 200 times larger than ordinary bacteria; they did not stain with aniline dyes, but gave a Prussian blue reaction. They appeared to comprise a central fine spicule with agglomerations around them. The spicule was probably asbestos enveloped in minute extravasations of whole blood or serous exudates.

Dr. A. C. HADDOW (Leeds) read a paper on clinical aspects of asbestosis among workers. A post-mortem examination of a worker who had died of the disease showed bodies in the lung similar to those described by Dr. Cooke. The average age at death was 41 years, and of employment at asbestos work two and a half years. Many workers, feeling that the job was unhealthy, drifted away from the factory. Such workers were not much under medical care until the later stages. They believed that symptoms began after five years. Several excellent radiographic photographs showed the density of the shadow was increased in the basal portions of the lungs, mostly flocculent masses with small cavities. The results of lung puncture showed the curious bodies, as also did the sputum. In a summary Dr. Haddow stated that tuberculosis was *not necessarily an accompaniment* of asbestosis; that asbestosis was generally discovered during an intercurrent attack of influenza; and that the disabled worker might continue at work for many years.

Dr. BURTON WOOD read a paper and showed slides, beginning with one of an *x*-ray film from a case of gold miners' phthisis with no tubercle. Films of radiograms from asbestos workers showed tiny mottled shadows. Such patients had extreme dyspnoea, some cyanosis, and slight cough. Tuberculosis was present in some patients, but in some it seemed to be secondary and made slow progress. Sir THOMAS LEGGE, as a retired medical inspector, expressed regret at the opportunities he had been obliged to forego, in part owing to the cramped nature of the medical inspector's powers in former years, and to the absence of team work with the medical officer of health, the certifying factory surgeon, the private practitioner, and the pathologist. Cases were reported in 1907, and a question was then asked in the House of Commons. Sir THOMAS OLIVER said that the bodies described in asbestosis were extremely large, and discussed the symptomatology. The interesting point was the long interval, as a rule, before symptoms became clamant. Referring to Dr. Bridge's plea for a revised nomenclature, he preferred to retain the present style, but avoiding the term "*pneumonoconiosis*."

SILICOSIS.

Dr. E. L. MIDDLETON (Home Office, London) opened his remarks by asking those present to inspect the exhibit of radiographic films and slides on view in the pathological museum. Silica might be inhaled without causing symptoms for a long time. It did not produce sufficient irritation of the nasal passages to cause immediate alarm. The first outstanding symptom was dyspnoea, but even when this was extreme the worker might persist at his employment. The cause of the dyspnoea was the increasing fibrosis. There was no curative treatment for the established disease. With regard to nomenclature, as legislation had been introduced the term "silicosis" was restricted to the disease produced by silica, no matter how derived. To achieve prevention research was needed in regard to all dusts. Dr. WATKINS-PITCHFORD asked Dr. Bridge if there was an explanation for the constant increase in the number of lead notifications and the diminishing number of deaths reported. Officially organized research was necessary in regard to occupational dusts. Siliceous dust was not noxious from its chemical action, but from its quantity and its tendency to produce lesions suitable for the settlement of tubercle bacilli. The elimination of the chances of tuberculous infection from the environment of persons exposed to dust was an important measure. Dr. P. HEFFERNAN (Derbyshire) said that in the lowest forms of life, silica was much associated with the animal matter. In the siliceous sponges there was a deposit of colloidal silica very much like the curious bodies Dr. Cooke had described in the lungs. In Germany silica was administered to promote fibrosis. How did the silica exist in the lung? The modern conception of cell metabolism and growth suggested that it was in the colloidal state. Recent researches showed that when silicosis and tuberculosis were associated, the silicosis was usually the precedent condition. The substances which appeared to delay the onset of silicosis were carbon and clay: the alkalis and soaps accelerated its onset. Both results were strongly in agreement with the colloidal action of silica. Three cases of very rapid fatal silicosis had lately been noted in young girls working in soap-powder works.

LEAD DUST.

Dr. R. E. LANE (Manchester) read a paper on lead dust and showed slides. He said that his experience inclined him to believe that absorption of lead was mainly by the respiratory system. An investigation in electric accumulator works had demonstrated many of the points previously discussed. The dust was very fine. Control took the form of improved ventilation, estimation of lead content of air, and study of blood films and lead content of urine. The blood films were taken six from each man—two at start of work, two at the end of the day, and two next morning. The red cells showing punctates were counted and the size of points—small, medium, and large—noted. Very interesting statistics were given: a large punctate count was found in correlation with other findings, yet the men's condition was not diagnosable by the usual routine examination. In new workers the punctate count rose very rapidly, and suggested susceptibility. Any sudden rise in the older workers suggested a new hazard or a failure of ventilation plant, whose efficiency had to be inspected daily. An upper limit of 3 mg. of lead dust per 10 cubic metres of air was found to be better than Sir Thomas Legge's standard of 5 mg. per 10 cubic metres of air in the workshop.

SECTION OF ANAESTHETICS.

Friday, July 26th.

CONTROLLABLE SPINAL ANAESTHESIA WITH SPINOCAIN.

AT the second meeting of the Section the chairman, Mr. A. L. FLEMMING, President of the Section, called on Dr. GEORGE P. PITKIN (New Jersey, U.S.A.) to open a discussion on controllable anaesthesia with spinocain. Dr. Pitkin's paper is published in this issue at page 183. Dr. FRANK A. KELLY (Detroit, U.S.A.) paid a tribute to the work of Dr. Pitkin. His paper is published at page 187. Dr. FALKNER HILL (Manchester), while realizing the value of the method, wondered whether the question of fall of blood pressure had not been unduly stressed. It was important to distinguish between fall of blood pressure due to surgical intervention and that due to the spinal anaesthetic. The latter could be counteracted by the Trendelenburg position. Any respiratory failure could be dealt with by artificial means. Was a temporary fall of blood pressure

therefore to be feared? He thought that the last word had not been said in this connexion, and that much work remained to be done. He did not approve the use of strychnine in the spinocain. The personality of the anaesthetist was a very big factor in the success of this method. He had obtained very satisfactory results with a combination of spinocain and general anaesthesia. The PRESIDENT remarked that the question of co-operation between surgeon and anaesthetist was of the greatest importance. The method undoubtedly had a very definite place in anaesthesia. He mentioned that active peristalsis was not necessarily stopped by a general anaesthetic. He had frequently seen peristalsis in progress during the course of an abdominal operation under general anaesthesia. Dr. PINSON said that, taking as criteria the points of view of surgeon, anaesthetist, and patient, only 45 per cent. of his cases had been really successful. He concluded, therefore, that the method was still in the experimental stage. However, in many of his cases he was ready to admit that he had been more than delighted with the results, especially with reference to the remarkable freedom from shock. Dr. SALISBURY (Northampton) said that technique was of primary importance in any form of spinal anaesthesia. He had used the heavy stovaine glucose solution with marked success. Dr. GERRARD (Manchester) spoke of his experience of spinocain in obstetric practice. Advantages were the softness and relaxation of the cervix and perineum, and the extremely easy time the patient had with the labour. He gave a warning about the use of pituitrin, which should not be administered till the head was in the pelvis. If given before, there was definite risk of rupture of the uterus. He hoped that the interest aroused by this new solution would lead to its more regular application to obstetrical cases. Dr. PITKIN replied.

CINEMATOGRAPH DEMONSTRATIONS.

Dr. A. G. SCHWARTZ (New York) gave a very interesting and instructive demonstration on the cinematograph, illustrating the technique that he employed in intratracheal methods of anaesthesia and in the Flagg method of resuscitation. Dr. F. L. RICHARDSON (Boston, U.S.A.) showed a film illustrating the teaching of anaesthetics with the aid of the cinema. He said that the cinematograph was a most useful adjunct to the teaching of anaesthetics, but should not, of course, be used to the exclusion of other methods. The film could be slowed down, if necessary, and important parts repeated. Dr. Richardson extended a hearty invitation on behalf of the Associated Anaesthetists of the United States and Canada and of the International Anaesthesia Research Society to anaesthetists in this country to attend the next Annual Meeting in Winnipeg. Dr. GEORGE EDWARDS showed a film illustrating the technique of administration and the action of avertin. In discussing the value of this drug in anaesthesia, Dr. Edwards said that it could be used to provide a deep narcosis, which was easily convertible into anaesthesia by the addition of very small quantities of ordinary anaesthetic. It was reasonably safe in doses up to 0.1 gram per kilogram of body weight. It eliminated nearly all the mental stress which accompanied the usual giving of an anaesthetic, and it had no effect on the respiratory tract, being excreted almost entirely by the liver and kidneys. It was certainly not an anaesthetic that anybody could give at any time. An experienced anaesthetist was required to control the superimposed anaesthesia. The routine of its administration made it difficult to use in hospital practice. In certain types of cases, especially where general anaesthesia was contraindicated, it was of definite value.

Reviews.

LIFE, GROWTH, AND REPRODUCTION.

PROFESSOR MAX ARON'S recent book on life and reproduction[1] has many merits; its author has the gift of clear exposition; it gives just what so many medical readers are in search of—an outline of the advances made in modern biology by a master who has a first-hand knowledge of its major problems. Professor Aron has studied life as revealed by the microscope; he finds the simplest cell to be a "prodigious laboratory" in which processes of a physical and chemical nature go forward as long as the cell is alive. He is convinced that we can know what life is only by following the clues provided by these physico-chemical processes. He expects, however, that even when the physicist and chemist have done their utmost there will still remain something for the biologist to explain.

Professor Aron's book is divided into three sections. In the first he describes the anatomy and physiology of the living unit of protoplasm called the cell. In particular he treats of the causes and conditions which determine cellular movement, cellular reproduction, and cellular differentiation. In the second section he reviews the manifestations of cell life as seen in the complex bodies of animals—particularly the phenomena of development and growth. In the third section he enters fully upon the problems of sex and reproduction. In all three sections we see the same method of approach. Professor Aron views all his problems as revealed upon the stage of his microscope, but views them with the eye of a physiologist—being a student of function rather than of structure. In all three sections of his book he first produces his evidence and then discusses his inferences in a manner which the youngest student may understand. He never loses sight of the needs of medical students and of medical practitioners. Again and again he returns to that enigma of growth—cancer.

It is impossible to summarize such a book as this—one which ranges so widely across the field of biology. A few of its conclusions may be cited. The author divides substances (hormones) which serve to co-ordinate the living processes of the body into three classes: (1) Differentiators—substances contained in certain cells, chiefly embryonic, which can cause other cells to change both in form and in function. (2) Growth regulators, such as are formed in the pituitary and sex glands, and the cortex of the adrenals. (3) Function regulators, such as secretin, insulin, etc. Professor Aron is convinced that even in the higher vertebrates the central nervous system takes a much more active part in regulating the growth of the body than is now supposed. He cites the experimental evidence which has led him to form this opinion. This conclusion is of particular interest at the present time, when evidence accumulates in favour of the belief that some nerves, such as the vagus, produce their functional effects (correlations) by producing a hormone at their terminal distribution. It begins to look as though, after all, the differences between the hormone system and the nervous system are not so great as they were supposed to be at first. Both systems seem to employ chemical messengers to produce their effects on the growth and action of the various parts of the body.

ANALYTICAL PSYCHOLOGY.

A NUMBER of Dr. C. J. JUNG'S recent contributions to psychology have been translated into English and published in two separate volumes. The first of these is entitled *Two Essays on Analytical Psychology*,[2] and its subject-matter is admittedly such as to make no ordinary demands upon the understanding of its readers. The author himself observes that, though he has done his utmost to smooth the path of understanding, there is one great difficulty which he is powerless to remove—namely, that the psychical processes and problems with which he deals are somewhat inaccessible to ordinary experience, and indeed to many are quite unknown. Thus these two advanced essays—the one on the unconscious in the normal and pathological mind, the other on the relation of the ego to the unconscious—will probably be most appreciated by

[1] *Vie et Reproduction: Notions Actuelles sur les Problèmes Généraux de la Biologie Animale.* By Max Aron, Docteur ès Sciences, Professeur à la Faculté de Médecine de Strasbourg. Paris: Masson et Cie. 1929. (6¼ × 9; pp. 366; 190 figures. 38 fr.)

[2] *Two Essays on Analytical Psychology.* By C. J. Jung, M.D., LL.D. Authorized translation by H. G. and C. F. Baynes. London: Bailhère, Tindall and Cox. 1928. (Demy 8vo, pp. xviii + 280. 10s. 6d. net.)

those who are already more or less conversant with the teachings of the school of psychology of which Dr. Jung is the founder, and who have actually applied the analytical methods and theories described to their own psychic life or that of others. The book is certainly one which requires to be expounded and discussed in circles interested in the views as to the nature and significance of the unconscious psyche therein developed.

The second volume, *Contributions to Analytical Psychology*,[3] contains more of interest to the reader who is not familiar with Jung's teaching than those referred to above. The opening chapter is highly technical, being concerned with an elaboration of Dr. Jung's theory of the *libido*, but in subsequent essays the writer applies his views to a variety of concrete problems of modern life. Papers on mind and earth, analytical psychology and *Weltanschauung*, women in Europe, marriage as a psychological relationship, the love problem of the student, the relation of analytical psychology to poetic art, the psychological foundations of belief in spirits, and psychological types are included. A contribution on analytical psychology in education, consisting of a series of lectures delivered at three meetings of the International Congress of Education, 1923-24-25, will interest the increasing number of those who are concerned in the problems of child life. Dr. Jung is strongly of the opinion that the causes of child neurosis should not be sought by analytical interference in the child's psychology, but rather in the atmosphere engendered in the home by the attitude of the parents, both to the child and to their own problems.

These works reveal their writer as an original and independent observer, who is gifted with keen psychological insight. How far Jung's formulations are calculated to give a new orientation to the problems of life and disease time alone will show. In his preface to the first of these books, Dr. H. G. BAYNES expresses the opinion that the discovery of the *collective unconscious* has added "yet another star to the constellation of major discoveries," and that the technique of its exploration which *Jung* has elaborated has incalculable effect on the course and character of human destiny. Though the reader may perhaps feel that these claims are pitched rather high, he will certainly find much in these volumes which is stimulating and suggestive.

OPERATIVE COMPLICATIONS OF CHOLECYSTECTOMY.

IN *Les accidents de la cholécystectomie*[4] M. SERGE HUARD of Paris gives a description of the untoward events that may occur during removal of the gall-bladder, under the two headings of those which are recognized during the course of the operation and can then be remedied, and those not noticed at the time but which, by giving rise to jaundice, biliary fistula, or peritonitis, necessitate further operation when the cause is revealed. Of the numerous accidents that may be due to operative intervention, wounds of the bile ducts, especially the common bile ducts, are much more frequent than damage to the hepatic artery or its branches; in the author's collected cases there were 64 records of biliary tract injuries and only 6 of wounds of the hepatic artery. Although wounds of the portal vein might naturally be anticipated, no example of this accident appears to have been put on record. In order to throw light on the occurrence of these operative accidents the normal anatomy of the biliary tract and the hepatic artery is first described, and then the abnormalities and pathological changes are considered in detail. After discussing the classical methods of performing cholecystectomy, such as those of Kehr and of Mayo and Moynihan, the author describes his new technique of removing the gall-bladder, and in a number of illustrations shows the six steps recommended, which, as borne out by six cases on which this form of operation was done by his chief, Professor Schwartz, renders it easy to avoid these operative complications.

PATHOGENIC STREPTOCOCCI.

THE *Annals of the Pickett-Thomson Research Laboratory*, the fourth volume of which has now been published,[5] are devoted mainly to bacteriology, protozoology, and biochemistry, and to recording photographically the whole range of bacteria and protozoa. The present volume, which is issued in two parts, deals with the rôle of the pathogenic streptococci in various diseases. In Part I an endeavour has been made to give as comprehensively as possible a historical survey of the part played by streptococci in acute rheumatic fever and its complications—chorea, erythema nodosum, and carditis. Part II deals with the rôle of streptococci in acute and subacute suppurative and chronic rheumatism, including rheumatoid arthritis and osteo-arthritis. The several monographs give a more or less complete summary of the researches which have been carried out since the beginnings of bacteriology, and are not confined to the streptococcal theories alone, but supply an account of most of the important views and theories held by various clinicians. The volume should therefore be of interest to the clinician as well as to the bacteriologist. The two bulky volumes are comprehensive in the sense that they contain all that has been, or at present can be, said on the subjects dealt with. With regard to rheumatic fever the author's conclusions coincide with those reached by Bulloch. "In spite of the numerous investigations which have been carried out, it seems to me that the etiology of rheumatic fever still belongs to the arcana of pathology, and, although what clinicians call rheumatic fever is probably a specific infective disease, the virus is not known." With regard to rheumatoid arthritis the chief bacteria which have been suspected are streptococci, *B. coli*, and staphylococci. The most definite researches yet published are those of Cecil, Nicholls, and Stainsby, who have isolated a streptococcus of the viridans group from the blood of a large percentage of cases. On the other hand, Warren Crowe believes that the disease is due to a special variety of staphylococcus, which he has named *M. deformans*. Both of these views require confirmation. In any case the disease is regarded as organismal; and endocrine, metabolic, and traumatic factors are considered to play a merely predisposing part. The authors adhere to the view that osteo-arthritis and the allied affections are associated with focal sepsis in the teeth and bowel, a view which the recent researches of Warren Crowe have tended to confirm. Senile degeneration and metabolic disturbances are not considered to play any part in the etiology, except as predisposing causes.

The authors have collected a very large amount of photographic material on the streptococci, and they propose to devote Volume VII to the publication of these accumulated photographs. They have solved the problem of taking extremely distinct photographs of the colonies on Crowe's medium, and they anticipate that Volume VII will form a complete atlas of the streptococcus group, which will enable the research worker with very little difficulty to differentiate between the various species.

INDUSTRIAL BIOCHEMISTRY.

A RECENT monograph by Dr. T. P. HILDITCH gives short accounts of all the most important catalytic processes used in modern industry.[6] Perusal of this volume brings home very forcibly to the reader the fact that modern civilization is rapidly becoming based on large-scale chemical processes, nearly all of which depend for their economic working on the use of catalysts. The most important chemical processes described are those employed in the synthesis of ammonia. It is interesting to learn that the world now gets 400,000 tons of fixed nitrogen annually from the air as compared with 312,000 tons from Chile nitrate, and that the world demand for fixed nitrogen

[5] *Annals of the Pickett-Thomson Research Laboratory.* Vol. IV. Parts I and II. The Pathogenic Streptococci: An Historical Survey of their Rôle in Human and Animal Disease. London: Baillière, Tindall and Cox. Baltimore: The Williams and Wilkins Company. 1929. (8½ × 11¼, pp. xv + 494; 2 figures; 18 plates. 42s. net per volume, post free).

[6] *Catalytic Processes in Applied Chemistry.* By T. P. Hilditch, D.Sc.Lond., F.I.C. Vol. II of a series of Monographs on Applied Chemistry. London: Chapman and Hall, Ltd. 1929. (Demy 8vo, pp. xx + 360. 16s. net.)

is increasing by 11 per cent. per annum. Some other catalytic processes of great importance are the production from water-gas of the petrol substitute synthol, the production of cellulose acetate, the hydrogenation of fats, and the use of accelerators for vulcanization of rubber. Many of the catalytic processes involve the use of very high pressures and in some cases of high temperatures. The author holds that the possibility of utilizing enzymes in industrial chemical processes deserves much more attention than it has received, because enzyme actions proceed under the ordinary conditions of temperature and pressure, and therefore their successful use would result in a great economy of fuel. The growing list of chemical compounds produced by enzyme action indicates the value of this branch of applied catalysts, and suggests that its employment will receive considerable extension in the future. The discovery of the Fernbach and Weizmann bacilli, which provided most of the acetone needed for cordite manufacture in the war, is one of the best known of the successes hitherto attained in biochemical commercial processes.

Biochemistry first developed as a science in the medical schools under the title of physiological chemistry. Orthodox chemists expressed their opinion of the new science in its early days by such terms as "blood and bone boiling," while orthodox physiologists were scarcely less contemptuous. The dominant position that biochemistry has attained in physiology and medicine will be familiar to all our readers, but probably only a few will have realized how important is the position that biochemistry has attained in industrial chemistry, and that its future importance promises to be very much greater. These facts are set out very clearly in the volume under review, and although some of it is occupied by technical details that are chiefly of interest to specialists, yet the volume is well worth the perusal of all who take a general interest in biochemistry.

NOTES ON BOOKS.

In *The Origins and the Growth of Chemical Science*[7] the theme is developed that the advance of chemistry did not take place at successive outbursts, but that its progress was uniform and gradual. The author, Mr. J. E. MARSH, has traced chronologically the successive stages of scientific discovery, and connected these with the expansion of theoretical views, showing how the erroneous theories of early times led to the growth of a knowledge of facts which in turn caused theories to be abandoned, modified, or remoulded. He reminds his readers that the ability to produce fire was the first introductory step to the practice of chemical operations, and, with fire as the experimental agent, philosophers passed forward from the stage of speculation towards that of deductive reasoning. Thus Aristotle's theory of four elements gave place to Paracelsus's theory of the hypostatical principles, which were held to be sulphur, mercury, and salt. This conception was followed in turn by the theory of phlogiston, which, as a working theory, was more substantially helpful than any previously devised. So little was the conflict between this theory and experience that even Cavendish, with all his experimental achievements and learning, saw no cause to abandon it. But on the discovery by Lavoisier that oxygen was a real substance, and not merely an assemblage of the negative qualities of phlogiston, the formulation of Dalton's atomic theory became possible. Meanwhile the theory of salt formation and the experimental work to which it directly led had become interwoven with the growing structure which ultimately developed into modern chemistry. Progress became more rapid in the earlier part of the nineteenth century, and the names of men grew more numerous who were destined to leave their mark on the work that followed them. The theory of atom linkage, introduced independently by Couper and by Kekulé, became the foundations of a structure that is even now receiving new additions; yet, as the author remarks in conclusion, the oldest real chemical theory, the theory of salt formation, which is mainly responsible for the growth of chemical science as it exists to-day, still presents many problems which await solution. Everyone interested in this side of chemistry should read this book; it is not too bulky for the ordinary reader; we think, indeed, that Mr. Marsh might well have enlarged his comments and added to his narrative of incident. For example, the derision met by Newlands when he first drew attention to what is now known as the periodic classification of the elements deserves to be noticed in any history of chemical theory.

Not until page 24 is reached does the reason become evident for the publication of Dr. LUTEMBACHER'S elementary study of the arrhythmias,[8] The author has already published cinematographic films and gramophone records illustrating the cardiac irregularities, and now he produces this "hybrid," giving the corresponding electro-cardiographic and polygraphic curves to illustrate the films and records. The book, he says, is not a treatise, it is not even a précis of electrocardiography. This is true, for apart from brief descriptions of the author's new and "prodigious" methods for the study of irregularities, one might describe the remainder of the text as being in the form of snappy captions.

Professor UDAONDO of Buenos Aires has written a small book on chronic ulcerative colitis,[9] in which the various aspects of this serious but obscure complaint are somewhat superficially dealt with. Over 200 references to the literature are given, and the ten plates at the end of the volume reproduce photographs showing the nature of the lesions produced in the disease, together with a number of x-ray pictures.

Dr. NEUBERGER'S book on the treatment of nervous diseases[10] gives a general and optimistic account of the subject with which it deals, written for medical men, supplied with a chapter on the treatment of the patients at the various watering-places appropriate to their special maladies, and ending with over twenty pages of references to the literature. It is well arranged and clearly written, and contains a well-digested mass of information.

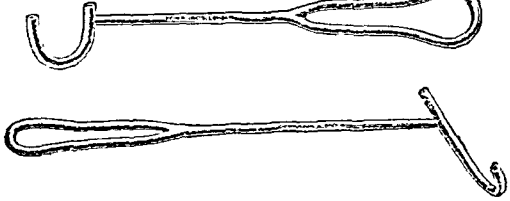
PREPARATIONS AND APPLIANCES.

A WIRE INTRODUCER FOR THE OPERATIVE TREATMENT OF FRACTURES.

MAJOR MEURICE SINCLAIR, C.M.G., R.A.M.C. (ret.), London, writes: The instrument illustrated herewith helps a surgeon readily to encircle the fragments of bone with wire. It is made in three sizes—large, medium, and small—to pass round various calibres of bones, and is best constructed of steel tubing to withstand the complex strains and leverages to which it has to be subjected during its passage around the bone; the original one was made from a curved section of a metal catheter, but it duly split longitudinally, and the softer metals are found to be not so satisfactory. The bore of the tubing should be smooth in order to reduce to a minimum the friction while the wire is being passed into it. The diagrams show that a curved length of tubing, which has a slightly smaller but rounded orifice (to prevent transfixion) at one end and is fully open at the other, is attached to a shaft at about an inch from the patent end. The shaft is fixed at an angle to permit of unobstructed vision, and to allow at first the instrument being placed length-



wise into the wound, and then, by a simple manœuvre of the handle, the orifice can be made to travel over the deep surfaces of the bone and come into view on the opposite curvature of the fragments. The wire is then easily passed into the opening, and by a combined movement of "wire-feeding" the introducer with one hand, and simultaneously withdrawing the instrument from the wound with the other, the impression is so conveyed that the instrument is being pushed out of the wound by the wire, and the surrounding of fragments is readily accomplished while the instrument is being gradually led back. Two twisted hoops of wire, which are fixed just within the extremities of the cleavage, are an excellent method of fixation for all closed spiral fractures; small plates and screws are not efficient in these cases, and should at any rate be removed as early as possible, but wire, in my experience, can remain in with safety.

The instrument has been made for me by Messrs. Down Bros., London.

British Medical Journal.

SATURDAY, AUGUST 3RD, 1929.

THE MANCHESTER MEETING.

THE observant cannot fail to note that in one important respect no Annual Meeting of the British Medical Association is like another. It becomes more and more clear, as the series lengthens, that on every occasion something of the native spirit of each town asserts itself and gives a distinctive colour to the programme and proceedings. This has been especially true of the Annual Meeting held last week in Manchester under the presidency of Professor Arthur Burgess, who, as his local colleagues and fellow citizens are proud to remember, is a Manchester man through and through. Our new President has been identified with the Victoria University and the Royal Infirmary during the whole of his career, and he has played a leading part in bringing to its present eminence the Manchester School of Surgery. His personality and his standing in the eyes of the profession of this country made the success of the 1929 Annual Meeting a foregone conclusion.

Overcoming of difficulties was, perhaps, one of the most noteworthy features of the week's proceedings in Manchester. Thus, for example, the serious obstacle of distance between such important centres as the Registration Hall and the University, where the nineteen scientific Sections held their meetings, was surmounted by facilities for free travelling over the tramway system provided to members by the Corporation, and the arrangement made with motor omnibuses and taxicabs by the local executive of the Association. The cordial interest taken in the meeting by the civic authorities of Manchester and Salford was indeed evident at every turn. No fewer than three impressive and enjoyable receptions invited members of the Association and their friends to realize that the city wished to honour to the best of its ability those who devote their lives to the prevention of disease and the alleviation of suffering. Public institutions of all kinds were thrown open, so that visitors could judge how this great centre of commerce and education, which prides itself justly on its modernity, is not only keeping abreast of the advance of knowledge, but also takes pride in treasuring in libraries and art galleries graceful memories of past ages.

The Sectional meetings were very well attended, and the sacrifices made by the University authorities to provide accommodation for so many simultaneous sessions deserve a special word of thanks. The subjects for debate had been chosen with great forethought and discretion, and the distinguished speakers drew audiences worthy of their efforts. Something of a note of home-coming was struck by the presence of the Mayo brothers, William and Charles, who received a warm welcome from the municipality and University, as well as locally at Eccles and in the scientific discussions. The Pathological Museum evoked particular admiration. It was obvious that very great care had been taken to render it fully adequate for a great occasion, and it played a prominent part in illustrating many of the subjects under consideration in the Sections. With so many Sectional meetings scattered through large groups of buildings, visitors might have expected some considerable difficulty in finding their way about; but this had been foreseen, and particularly good arrangements were made to direct them to the theatres and classrooms, medical students lending willing aid in this and in other respects. One difficulty alone seemed to be insuperable: many of those wishing to get the most out of the three days' scientific business complained gently that it was really very hard to decide which discussion to attend out of so many proceeding at the same hour. It may be added, however, as some partial compensation, that the summaries appearing in this and subsequent issues of the *British Medical Journal* will enable an idea to be obtained of the ground covered at each session. Moreover, the introductory papers of each debate will be printed in full in these columns between now and the end of the year. The subjects to which they relate are undoubtedly topical and of much interest from the point of view of general therapy and diagnosis. It was noticeable that throughout all the discussions theoretical considerations gave way as far as possible to practical details, and this, no doubt, accounts in large measure for the keen attention with which the clinical and scientific proceedings were followed.

As we have indicated, a feature of this Annual Meeting—the fifth to be held by our Association in Manchester—was the excellence of its organization. This was the result of many months of thought and unselfish labour on the part of those chosen by their colleagues to plan and carry out the local arrangements. Among the corps of willing workers who associated themselves with the President and Mrs. Burgess a few outstanding names must be mentioned here. Dr. E. Bosdin Leech and Dr. R. G. McGowan, the indefatigable honorary general secretaries, supported between them the main fabric of the meeting. By harmonious division of labour and infinite care for detail they ensured the smooth running of every part of the machine. No one who has not had personal experience behind the scenes can realize how great a burden is borne by the local secretaries of a congress such as this. Beside them, always genial and ever regardful for sound finance, stood Dr. John D'Ewart, the honorary treasurer of the meeting. Two other names among many that deserve to be placed on record are those of Colonel F. H. Westmacott, chairman of the Entertainments and Transport Committee, and Dr. E. M. Brockbank, who, as editor and part author of the *Book of Manchester and Salford*, has provided every visitor with a worthy memento. By their efforts to achieve success for the ninety-seventh Annual Meeting the local executive have played a notable part in forwarding two of the main objects for which the British Medical Association exists—namely, the advancement of medical science and practice, and the promotion of good fellowship among members of our profession.

EARLY DIAGNOSIS OF CANCER OF THE STOMACH.

THERE is a fairly general belief among the medical profession that cancer of the stomach is more common than formerly. Pathologists, however, point out that in recent series of consecutive post-mortem examinations the incidence of cancer of the stomach is found to be about one in every fifty-five necropsies, a figure much in accord with earlier statistics. A big factor, no doubt, in the apparent increase is that there are now much greater facilities for examination of gastric cases. The advances in chemical knowledge and in radiological technique have made diagnosis easier in cases of cancer of the digestive tract, which was

formerly invisible, and therefore less obvious, than cancer in such accessible situations as the breast, the uterus, and the tongue. Further, the emphasis laid by the leaders of the profession, physicians and surgeons alike, on the need for early recognition of cases of cancer, at a time when the only treatment available—extirpation—is still possible, has awakened the sense of responsibility of practitioners to the prevalence of the disease and its sinister course if allowed to make headway. Again, the education of the people has made possible a general dissemination of knowledge of the facts of cancer, and has led the layman to expect, and rightly to expect, increased acumen in medical diagnosis. The disease is thus constantly in the minds of those called upon to see and treat digestive disturbances in their patients. It does not come as such a surprise, and, being sought for, is less often missed. It is not enough to diagnose cancer of the stomach, however; it is essential to diagnose it as early as possible. In its natural evolution the course of the disease is short and the end sure. It is rarely that more than two years elapse before the inevitably fatal termination.

Cancer of the stomach starts as a local disease in the mucous membrane, or sometimes in embryonic epithelial remains in the submucosa, and at first spreads centrifugally in the lymphatics of the submucosa, producing a local rigidity. Although in most cases gastritis is found associated with cancer, it is most likely a toxic condition secondary to the growth. The view that there is a form of gastritis preceding the onset of cancer is not generally accepted. Cancer of the stomach does not commonly follow on ulcer. In the pathological studies of Stewart, and of Dible and Morley independently, only 6 per cent. of cases of cancer of the stomach examined microscopically showed evidences of previous ulceration. It is, as a rule, by later spread that the mucous membrane becomes eroded and ulcerated, or the peritoneum invaded. The lymphatic glands along the curvatures are soon involved, and from these dissemination results in implication of the liver, and the mediastinal and cervical glands. Surgical removal is the only method of treatment; to be successful this must be carried out at a stage when the disease is localized and complete extirpation is possible.

It is unfortunate that in the textbooks the cardinal symptoms of cancer of the stomach are those of the established disease, when it is usually too late for effective surgical intervention. Wasting, vomiting, cachexia, anaemia, and tumour form a syndrome in which diagnosis is easy, but at this stage rarely any except palliative measures can be adopted. In looking back over the histories of such patients, however, there are often to be found clues which should have aroused suspicion, and it is in the suspicious stage that every ancillary aid should be used. Each suspected case should be investigated fully; by awaiting developments valuable time may be lost. Indigestion starting in a patient in middle life or later is suspicious, for two-thirds of the cases occur in those who have been hitherto unaware of digestive trouble. The indigestion may take many forms, and almost all the symptoms of gastric disturbance may be found at times in cases of cancer of the stomach. The commonest are loss of appetite, discomfort in the upper abdomen—either constant, or more or less related to the taking of food—flatulence, heartburn, and eructation, and regurgitation of stomach contents. The discomfort may be a mere sense of fullness or weight in the stomach, or may be actual pain. It is usually not severe; but the persistent, though mild, dyspepsia should arouse suspicion. In about one-third of the cases digestive trouble of long standing precedes the onset of cancer, though in less than 10 per cent. is there a history of ulcer preceding cancer. Faced, then, with an apparently causeless indigestion in a patient of the cancer-bearing age, or with suspicious symptoms in one who has long suffered from indigestion, the practitioner must take every means possible of clearing up the doubt. Objectively there may be little evidence of trouble, and ordinary physical examination may elicit little of importance. A feeling of resistance of the left upper rectus abdominis muscle may, however, give an early suspicion of beginning peritoneal involvement before any tumour can be palpated. The chemistry of the gastric contents may be normal, and occult blood absent from the faeces. Indeed, abnormal results with these tests show that the mucous membrane is already much involved. If, however, the chemical findings are correlated with the clinical findings they are often of considerable value. No biological tests of the serum and blood are yet available. Direct inspection by gastroscopy is a difficult and often dangerous procedure, which can rarely be applied. It is by x-ray methods that gastric cancer may be recognized considerably earlier than by any other methods. Filling defects caused by mucosal swellings which project into the lumen of the stomach, or interruptions of the normal striae of the mucosal folds in the partially filled viscus can be demonstrated. In addition, loss of flexibility of the wall, or the arrest of peristalsis in a small area infiltrated by growth, may be the earliest sign to arouse suspicion that all is not well with the stomach, though a similar picture may be obtained in some cases of ulcer or perigastric adhesions.

The place of x rays in the diagnosis of early carcinoma of the stomach was discussed by the Section of Radiology and Radio-Therapeutics at the Annual Meeting of the British Medical Association held at Manchester last week. The Section was fortunate in having as opener of the discussion Professor Martin Haudek of Vienna, who has already contributed greatly to advances in our knowledge of the application of x rays to gastric diseases. Professor Haudek, in his introductory address, which is published in full at page 173 of this issue, gave a masterly description of the technique which should be adopted in the examination of patients with suspected disease of the stomach. This will be studied with interest by all workers on the subject. Professor Haudek uses the double-meal method, and examines the patient first for residues in the stomach four hours after an opaque meal. Many workers would prefer, when possible, to observe the emptying time of the stomach, as may be done by observation at suitable intervals after a single meal, if the patient remains close at hand for several hours after the meal is taken, since the time at which the stomach is emptied cannot be estimated from the residue at four hours. The examination is then continued by observing the filling of the stomach with another barium meal, the patient standing behind the screen. When the meal is finished the patient is placed in suitable postures for demonstrating each part of the stomach in the filled and partially emptied condition. Emphasis is laid by Professor Haudek on the need for care in examining the cardiac end of the stomach at the upper margin of the barium meal to prevent mistakes. The advantages of the prone position in defining the contour and motility of the lesser curvature are not only the increased filling of the lesser curvature in this posture, but also that with the screen at the back slight magnification occurs of

small defects. Professor Haudek, too, insists rightly on the need for photographs at each stage, both as a permanent record and as a verification of surmises made in screening. He has not, however, used the cinematographic camera, which in the hands of others has given results otherwise unobtainable in showing lack of flexibility of the stomach wall or hesitating peristalsis—results that are of the greatest value in the diagnosis of those prepyloric ulcers and growths which are often so difficult to identify. Portable cinema cameras are now in use which enable a series of observations to be made with the patient in any position desired.

Such a complete *x*-ray examination takes time. Professor Haudek spends at least half an hour on each case, and does not examine more than eight or ten patients a day. There is a very real danger that a hurried and incomplete *x*-ray examination which fails to reveal an early lesion may give a false sense of security to doctor and patient alike; valuable time may thus be lost, during which the disease advances so that successful treatment by removal becomes impossible. Although 40 per cent. of cases of cancer of the stomach are now successfully operated upon, in the greater number laparotomy is too late. Professor Haudek concludes that none but men equipped with a sound knowledge of pathology, clinical medicine, and radiology can ever help cancer sufferers to the earliest possible diagnosis and cure of their disease. Of such men Professor Haudek himself is clearly in the front rank.

With all the immense help afforded by a complete *x* ray examination in avoiding late and useless laparotomies and in giving evidence for early exploration, it is, however, with the patient's medical attendant that the decision ultimately rests. It is only after carefully considering all the data that such a decision should be made; in cases where doubt arises laparotomy should be advised. The patient and his relatives will naturally expect an opinion as to the outcome of such an operation, but the course of action to be taken may have to be determined finally at the consultation on the operating table, when the state of matters is laid bare. Laparotomy should not be lightly undertaken as a mere exploration, nor should it be deferred when, after due consideration, doubt remains. As a famous surgeon who has recently passed from among us used to say: "Gentlemen, I am not afraid that you will cut too deep; all I am afraid of is that you will not cut soon enough."

ANNUAL MEETING NOTES.

The Annual Representative Meeting.

Monday, July 21st.

In the *Supplement* this week we conclude publication of the full report of the Annual Representative Meeting at Manchester. The short notes printed below, supplementing those printed last week, are intended to give, in very general and informal terms, an outline of the course of the discussions during the latter part of the meeting.

The debate on the report of the Psycho-analysis Committee, resumed at the beginning of Monday's session, followed the lines set by Dr. Langdon-Down in his admirably lucid and balanced introduction of the subject on Saturday evening. The course of the discussion made it clear that Dr. Biggs had spoken for the large majority of the representatives in his effective intervention at the beginning of the debate. With respect and sympathy for the patent sincerity with which Dr. Parry, Dr. D'Ewart, and Mr. Turner voiced what Dr. Gordon characterized as an "article of faith," the representatives showed themselves determined—soberly, and with full realization of the dangers of exploratory dealing with the human mind—to vindicate the scientific method in this as in other fields of therapeutics. In the absence of conclusive data the report called for no final verdict on any undecided issue, and none was expressed, but there was ample testimony to the practical value of the report. This was accepted as discharging the reference to the committee, and with the thanks of the Representative Body to its members. With the exception of the Psycho-Analysis and Parliamentary Elections reports, the matters brought before the meeting on Monday were singularly unproductive of controversy. They were, nevertheless, neither of minor importance nor lacking in interest. The report on Poor Law reform, for example, gave Dr. Brackenbury an opportunity, not only of explaining the action taken by the Council during the legislative stage of the present recasting of local administration, but of emphasizing the importance of local vigilance and initiative in the "scheme stage" now reached. So the Science report allowed Mr. Souttar to make a review which, notwithstanding its brevity, demonstrated the direct value to the general practitioner of the scientific work undertaken or promoted by his committee. The report on medical benevolence, presented by Dr. Douglas in the regretted absence through illness of Dr. Walker, raised no new issues. The discussion showed a need no less urgent than heretofore, and a response little less inadequate, despite the efforts of the Charities Committee and of some Divisions. The lead given by Manchester in this connexion was not in dispute. On the Ethical report, presented by Dr. Langdon-Down, the Representative Body expressed its hearty sympathy with Dr. Lyndon, who was absent through illness, although he had succeeded in attending the earlier sessions of the meeting. The Overseas report, presented by Sir Jenner Verrall in the unavoidable absence of Dr. Paterson, was taken, as usual, after the lunch interval, a procedure which gives the Representative Body leisure to make the acquaintance of some at least of the overseas representatives. The speeches showed warm appreciation of the work of the Association overseas, and a marked agreement as to the value of visits, whether from members of the central staff of the Association or from leading members of the profession in this country. The Naval and Military report, which contained no controversial matter, enabled Dr. Goodbody to comment on the efficiency of the Association's intervention in service matters, and Dr. Brackenbury to emphasize the spirit in which such intervention is undertaken.

The outstanding item on the agenda for the day was the report on encroachments on the sphere of private practice. Its reception demonstrated once again the urgent need for patient investigation of facts as a preliminary to the formulation of policy. The undisputed acceptance of the main conclusions of the committee, without modification or addition, showed the thoroughness of its deliberations, no less than the comprehensive character of the Medical Secretary's investigations and report, which supplied the basis for those conclusions and earned the unstinted appreciation of the meeting. In view of the atmosphere of suspicion and dissatisfaction in which the inquiry was set on foot last year, the general agreement on the report was surprising. Discussion was barely sufficient to dispel a doubt as to the interest of the Divisions in a question of primary importance. Dr. Le Fleming's report on the position of the Parliamentary Elections Fund provoked a lively debate, and one which showed a greater diversity of opinion than any which had preceded it—presumably because it turned upon political rather than professional conceptions. It was perhaps due to that very diversity that the suggestion of Brighton,

that a fund which has admittedly failed to secure adequate financial support after a reasonable period of trial should be wound up, was rejected.

Tuesday, July 22nd.

The Representative Body met on Tuesday with a sufficiently heavy agenda for the short time at its disposal, but succeeded in completing its business according to programme, without having recourse to evening sessions or special limitation of speeches. Votes of thanks to those responsible for the success of the meeting were taken early, in order to ensure a more dignified procedure than has sometimes been attained, and there was ample time to accord a hearty welcome to Dr. Bazin and Dr. Primrose of the Canadian Medical Association, who attended part of the session. A few words of farewell addressed to the meeting by Dr. Milner Moore of Lewes and East Grinstead were received with hearty applause, and members echoed the hope expressed by the Chairman that in the event of his withdrawal from their deliberations on the disbanding of the Division he has so long represented they would yet see him at future meetings.

On the report of the Ophthalmic Committee Dr. Wallace Henry urged once again the great public and professional importance of the Association's scheme, now being brought into operation. An amendment from Dundee was withdrawn after it had served to emphasize the drawbacks of existing conditions, from which the scheme offers a hope of escape. On the Organization report, a motion by Lancashire and Cheshire, ably presented by Dr. Matthews, secured a reference to the Council of the problem of dealing with inactive Divisions. The Welsh and Irish reports were presented with admirable and admired brevity. On the Scottish report Dr. Buist was able to announce a gratifying measure of success in applying the Association's scale of salaries in Scotland. The Public Health and Poor Law report, and the amendments put forward by Bath and Newcastle, gave rise to a discussion of considerable interest. It allowed Dr. Lewys-Lloyd and Dr. Brackenbury to explain the difficulty and urge the importance of finding some means of securing for the community under the Local Government Act the continued services on local authorities of medical practitioners. Moreover, it drew attention to the importance of the quality of the supply of vaccine lymph available for use in private practice. It was made very clear that, whatever the statutory obligation and administrative activities of the Therapeutic Substances Committee, the standardization of the lymph available to private practitioners is not considered effective by the profession at large, and that the public health is affected by that fact. A recent unfortunate case was the occasion of an instruction to Council, on the motion of Gateshead, to take steps to secure from local authorities, not only the adoption of superannuation schemes, but also the provision for compensation in cases where infection incurred in the discharge of his duties causes the death or permanent disablement of a public health officer. There was no discussion on the reports on lunacy and mental disorder, the international medical sea code, or puerperal morbidity and mortality, all of which were confined to indicating compliance with instructions given by the Representative Body last year.

The motions not related by the Agenda Committee to any section of the Annual Report of Council have a special interest as an index to the vitality and initiative of the Divisions. A motion by Marylebone on the provision of institutional accommodation under the Mental Deficiency Acts, and one from Bath and five from Windsor dealing with the treatment of nervous and borderland cases, and referred to the Council on the proposal of Dr. Gordon and Dr. Elizabeth Casson, deserve special mention as dealing primarily with the welfare of the public. Another group of motions directed to safeguarding the independence of the private practitioner was received with less enthusiasm. Two of these were not accepted, while the third, which anticipated the creation of a whole-time salaried State medical service, was reduced to a simple reaffirmation of accepted policy. The discussion on this motion elicited some curious estimates of the general outlook of the younger members of the profession in various parts of the country. On a motion by Gateshead the meeting showed itself fully alive to the need for securing adequate conditions of service for Poor Law medical officers under the new machinery of local government, and the danger of prejudicing the settlement by untimely reference to existing conditions. A somewhat involved motion by Brighton, asserting the interest of the patient in choosing the class of institution to which he should be referred for treatment, was, after clarification of its purpose by Dr. Brackenbury, accepted in an amended form. From Marylebone came an interesting suggestion for a definition of the Association's policy on medical privilege. On the revised standing orders—in accordance with which the business of the meeting had been transacted with no small success, under the skilful and patient chairmanship of Dr. Hawthorne—the Representative Body was not prepared as yet to pass judgement. Some fear was expressed lest the new procedure should curtail existing facilities for the discussion of motions from Divisions and Branches not bearing on any particular section of the Annual Report, and the question was postponed till next year.

Throughout this year's meeting the debates were maintained at an unusually high level. There was little confusion of thought or inadequacy of expression, and attention was concentrated on the main issues, effective use being made of the appropriate machinery for public discussion. To this result the acoustic properties of the Milton Hall doubtless contributed, but it must have been largely determined by adequate preliminary consideration in the Divisions of the matters under review, as well as judicious presentation of the several topics, both in the published reports and in their introduction to the meeting.

Popular Lecture: Experiments on Frogs and Men.

The Popular Lecture, by Professor A. V. Hill, D.Sc., F.R.S., of University College, London, was delivered on Friday evening in the Free Trade Hall. The President (Professor Burgess) was in the chair, and the spacious hall was comfortably filled. Although the provocative title might have been expected to stimulate opposition in anti-vivisectionist circles in Manchester, only one voice was raised in what appeared to be dissent.

Professor Hill began by pointing out that man was an inveterate experimenter. Every new adventure on which he had embarked through the ages, every change in his social and economic and political condition, had meant experiments upon his bodily frame and organization, experiments sometimes successful, but often followed by disaster. The search for truth, for wealth, for power, for control of surroundings, even for comfort and the avoidance of suffering or disease, was impossible without experiment. Nature also was continually performing experiments. Every patient represented an experiment performed by Nature, often an apparently cruel and ruthless experiment. Nature was an extremely bad experimenter; she was, in fact, the imaginary vivisector of antivivisectionist literature, whose experiments were made without mercy or apparent cause. So badly and casually performed were they, and so ill controlled, that it was often impossible to reason accurately from them at all. Small wonder that for thousands of years medical knowledge advanced relatively so slowly when it had to be based only on experiments such as those which Nature provided. In most of Nature's experiments the variables involved were all confused with one another, the factors at work could not be disentangled,

the results were not clear-cut. The only way in which the confusion might be avoided was by comparing the results of Nature's casual, random, and complex experiments on human beings with those of simple properly controlled experiments on animals. Such a comparison was the means by which, in the last few hundred years, and especially in the last seventy-five, medical science had made such startling progress. After quoting what Claude Bernard had to say about the experimental method, the lecturer said that current thought was returning to Bernard's conception of medicine as an experimental biological science, of which zoological vivisection was, and was likely to remain, an integral part. Bernard's own work had shown how a few controlled experiments on living animals might shed light on the countless uncontrolled experiments of Nature on living man. In 1851 Bernard made his first communication on the effect of dividing the cervical sympathetic nerve in the neck of a living animal. The ensuing rise of temperature on the affected side—a surprising and quite unexpected phenomenon—led by a long series of researches directly to the present knowledge of the vaso-motor system. This was a vivisectional experiment, such an experiment as some would prohibit to-day, willing though they might be, when they went to a medical man, to profit from similar experiments in the past. True, the knowledge thus gained might have been arrived at in the course of time in other ways, but up to the day of Bernard's experiments all Nature's own experiments, seemingly cruel, carried out continuously on suffering men and animals, had passed before the eyes of eager observers without suggesting more than the dimmest idea of such an action of nerve fibre on blood vessel. Would anyone to-day, had he the power, give the pain which Bernard's discovery abolished in order to save the pain by which the discovery was made? If so he might call himself the friend of animals, but he was an enemy of mankind. Nearly all fundamental knowledge in the medical sciences had, in fact, sprung from experiments on living animals. It was by vivisection, as Harvey said, of "toads, serpents, frogs, house snails, shrimps, crevisses, and all manner of little fishes" that modern physiology and modern experimental medicine were born. In using the various animals in his discovery of the circulation of the blood, Harvey assumed unconsciously the fact of evolution. He realized, being a sensible person, that the hearts of snakes or crabs did not differ so much from those of man and the higher animals that an investigation of the former could throw no light on the latter. There were differences, of course, but they were more apparent than real; the fundamental properties of the ultimate living units—that is, of the single cells which built up the various organs—were surprisingly alike. By methods of comparative physiology or of experimental biology, by the choice of a suitable organ, tissue, or process, in some animal far removed in evolution, considerable light might be thrown upon some function or process in the higher animals or in man.

The lecturer went on to refer to other discoveries the result of animal experiment. How safe would surgery be to-day had the researches of Pasteur on animals and their applications by Lister to man never been made? The basis for the taking of blood pressure was laid by Stephen Hales as a result of experiments on living animals in the parsonage at Teddington. The knowledge of the thyroid gland was due to the so-called vivisection of animals and man. Very many branches of surgery, the ligature and suture of arteries, the use of artificial respiration, the treatment of diphtheria, tetanus, syphilis, all depended, in the researches which had led to them, upon experiments on animals. Not only did the discovery of insulin rest absolutely upon experiments on animals, but its supply could not be maintained without continual experiments on mice and rabbits for its standardization. The liver treatment of pernicious anaemia was the result of experiments on dogs; the discovery of vitamins similarly depended on tests made upon animals. The object of the antivivisectionists was, frankly, to put an end to all this research. It was not inconceivable that they might get their way. There were States in America where the teaching of evolution was forbidden, but England ought not to be allowed to become the laughing-stock of the world like Tennessee.

Professor Hill then turned to consider the physiology of the nerves of frogs and its bearing upon the characteristics of the human nervous system. He referred to the work of Professor Adrian and his pupils; their experiments, conducted with splendid simplicity and skill, had left no doubt of the quantitative nature of sensory response. With the aid of the tools which wireless engineers had provided, single nerve waves in single nerve fibres could be amplified and recorded, and a whole new world of hurrying activity was opened up to analysis. Not only could the separate waves in an afferent nerve fibre be registered photographically, but they could even be transformed into sound and heard in a loud-speaker. The physiology of sensation had taken a new jump forward, and nobody with a particle of scientific imagination could doubt that this new knowledge would have important bearings upon the pathology of nerve affections. This research had also developed on the efferent or motor side, and it seemed now from Adrian's work that variation of the number of fibres involved in a muscular response was only the coarse adjustment; the fine adjustment was due to a graduation of the frequency with which the muscle fibres were excited by their nerves. These fundamental facts, bearing upon the theory of the working of the nervous system, had been established by experiments on frogs and other animals, and confirmed by experiments on man, and it could not be long before they affected the pathology of the nervous system. He was sure that they had involved for the animals no pain worthy of the name. Professor Hill described how, in a recent experiment of his own, he had examined the limb nerves of Maia, the spider crab, and had recorded their electric response to stimulation. The nerve, to his astonishment, was found to be obviously and highly fatigable. It was almost impossible to fatigue a medullated nerve, but the non-medullated nerve of Maia could be fatigued almost to complete exhaustion by stimulation for a few minutes. Fatigue at the point of stimulation was greater than at a distance from it. In the presence of oxygen the nerve recovered; in the absence of oxygen it did not. The central nervous system consisted largely of grey matter—that is, of nerve cells and of non-medullated nerve processes; only to a minor degree could its properties depend upon its medullated fibres. In the fatigability, in the large amount of energy used, in the dependence on oxygen, in the varying degree of electric polarization of its surface, might there not be seen, in the crab's non-medullated nerve, more faithfully reproduced, the properties of the central nervous cells, rather than in the simple medullated nerve of the frog?

Finally, Professor Hill spoke of the general advantage of unbiased experiment and observation, as against the danger and folly of scholasticism and unverified hypothesis. "If you wish to find out about the stars you must observe the stars, you must experiment with the materials which you suspect the stars to contain, you must try to reproduce, and to experiment under, the conditions which obtain in the stars; you will not be content merely with pictures of the sky at night." Living processes were subject to the same determinism as the phenomena of the inorganic world. The only difference was that the problems of physiology, taken in its widest sense, were far more difficult and complex than those of the so-called exact sciences. The problems of biology required greater, and not less, experimental skill. Much of the field of biology was unexplored, and the

present need—which would remain for many years to come—was for exact quantitative experiment on living creatures and tissues. One objection to the use of animals in experimental medicine had been the anti-evolutionary prejudice, but to-day the conclusion can hardly be seriously contested that medicine and human physiology were branches of experimental biology. "To-day there are unlimited opportunities for experimental biologists, adequately schooled and disciplined in hard reasoning and exact methods, in its border sciences. From frogs to elephants upwards, from frogs to filterable viruses downwards, we may take our choice, according to the demands of the experiment: and the end of it is man. Puny, fearful, unreasonable, selfish he may sometimes be, yet possessing always elements of nobility, courage, kindness, and devotion such as no other animals have, which make him, as was said nineteen hundred years ago, 'of more value than many sparrows.'"

The Pathological Museum.

Of the many activities of the Association at the Annual Meeting, none provides a more varied or instructive fare than the Pathological Museum, and this year proved no exception to the established rule. Complementary, as the exhibits were in many cases, to the discussions of the various Sections, they gave to those who can only visit one or two sections at least a glimpse of the work that is being done in others; and memory of them will add greatly to the interest with which the published account of the Sectional activities will be read. In the Section of Medicine the number of exhibits was small, and chiefly devoted to rare cardiac abnormalities; but the graphic records of heart murmurs and the Korotkow sounds by Drs. Crighton Bramwell and R. Ellis were fascinating examples of the newer methods of approach in cardiac problems. Diverticulitis, which was the subject of discussion in the Section of Surgery, was admirably illustrated by some specimens and large microscope slides by Mr. Lockhart-Mummery; a display of cystoscopic drawings of the normal and pathological appearances of the bladder and ureter were of great interest to many whose experience necessarily lies chiefly in general surgery rather than in a specialized branch. The largest division was naturally that devoted to the Section of Pathology and Bacteriology. Here a fine collection of specimens of the intestinal tract, showing the association of malignant and benign tumours in the same individual, was clearly suggestive of a more intimate connexion between the two conditions than mere coincidence; the specimens exhibited by Dr. Dukes were designed to show the early change from simple adenoma to carcinomatous invasion. Yet, as Professor Leitch pointed out, museum preparations may be misleading, for although the twelve specimens he himself showed were all examples of this same association, yet he entirely dissented from Dr. Dukes's conclusions. Dr. Cappell's beautiful demonstrations of the reticulo-endothelial system by vital staining left a lingering regret that the ordinary worker, with no special experience of a rather elaborate technique, is so completely dependent upon the expert in matters of interpretation. In addition, a large number of tumours and other lesions of the alimentary tract were shown. Among a large number of specimens contributed by the Manchester University Pathological Museum, those dealing with diseases of the haemopoietic system and the genito-urinary system attracted much attention. The appearances of the bone marrow in pernicious anaemia and leukaemia were excellently shown, and contrasted well with the two types of carcinomatous invasion—osteoplastic and osteoclastic—and we were reminded here of the oft-forgotten help that *x*-ray examination of the bones may give in the diagnosis of anaemia dependent on unsuspected or undetected carcinoma. Many pathologists must have wished that all the kidneys they had to deal with showed as clearly the destructive points to be demonstrated as the nephritic kidneys in the genito-urinary section. In the Section of Occupational Diseases the museum provided an illuminating insight into the special diseases to which so many industrial workers are as yet inevitably exposed. Mule-spinner's cancer—the subject of much special investigation by the Manchester Committee on Cancer—was extremely well illustrated, and this exhibit derived additional interest from Dr. Brockbank's brochure on cotton-spinning that was presented to members attending the meeting. Oil and tar cancer and dermatitis were fully represented, and the specimens illustrating asbestosis of the lung and silicosis were of special interest to those who had heard the discussion on occupational dust. The majority of the specimens devoted to the diseases of children were of tumours or congenital abnormalities, the chief interest of which lay, fortunately, in their comparative rarity; on the other hand, Dr. Catherine Chisholm's series of radiographs illustrating the curative effect of cod-liver oil in the treatment of rickets was a pleasant reminder that medicine has its triumphs as well as surgery. Professor Martin Haudek's series of lantern slides illustrating the use of *x* rays in the early diagnosis of cancer of the stomach were the basis of a discussion in the Section of Radiology; they showed not only the invaluable help that *x* rays may give, but also the need for expert technique and expert interpretation if full advantage is to be taken and mistakes avoided. A series of *x*-ray slides was also used to illustrate the treatment of apical dental infections, both by the surgical method of resection of the root apices and by the use of antiseptics sealed into the pulp cavity. In the specimens of foot-and-mouth disease, anthrax, glanders, and tuberculosis in the cow, which Professor Maitland contributed from the Public Health Laboratory, members had a very welcome opportunity of seeing conditions of which they hear a good deal but mostly see very little. From the technical side of museum preparation and arrangements there were no very novel suggestions, but Dr. McCartney's exhibits, all mounted by the "slab" method, showed how conveniently specimens could be preserved in this way, and how excellently it serves its purpose for many types of specimen.

When the Reception Room at Manchester closed on Friday evening, July 26th, 1,925 members had registered as attending the Annual Meeting.

SILICOSIS IN NEW YORK AND SYDNEY.

SEVERAL papers have been published recently showing the widespread interest aroused in the effects of inhalation of siliceous dust—an interest which will be quickened by last week's discussion at Manchester in the Section of Occupational Diseases. We use the word siliceous advisedly, because soon probably the terms "silicosis" and "asbestosis" will be confined to the effects of inhalation of free silica dust and asbestos dust, and some other term (possibly "silicatosis") will be applied to those due to the less injurious dust from silicates. Already it is claimed that radiological differentiation of these is easy enough. The most ambitious paper comes from New York.[1] Here a haphazard study of 208 volunteers from among the two or three thousand men employed in drilling, blasting, and excavating rock of a total silica content varying from 56 to 94 per cent. was carried out. Diagnosis was based entirely on the *x*-ray findings. The remarkable statement is made early on in the report that "physical signs in the lung were noted, but were not given

[1] Silicosis among Rock Drillers, Blasters, and Excavators in New York City. *Journal of Industrial Hygiene*, vol. xi, No. 2, February, 1927, pp. 37-81.

diagnostic weight because of the well-known fact that in this condition they may be absent or misleading." This is contrary to the wide experience in Great Britain from examination of over 1,000 pottery and sandstone workers, where fibrosis of the lungs was diagnosed by medical examination at a period of employment earlier than that at which silicosis has been found by radiological examination. But let that pass; the results brought to light in this random group by reliance on the means adopted are sufficiently startling. Twenty-three per cent. of the workpeople showed evidence of ante-primary silicosis, 19 per cent. of first stage silicosis, 7 per cent. of second stage silicosis, and 8 per cent. of third stage. Second and third stage silicosis occurred four times as frequently among underground workers as among open-air excavators. Apparently at present no protection whatever is afforded to these workmen in the shape of ventilation in the tunnelling operations, or by prohibiting, as is done in South Africa, the use of dry jack-hammer drills. The disabled receive no compensation. No wonder the conclusion is reached that "silicosis constitutes a serious health hazard" to the New York drillers and blasters, and immediate action is urged by the representative committee which arranged the inquiry, as 5,000 men are about to be employed for six years in tunnelling at a depth of 500 ft. through twenty miles of Manhattan and Bronx siliceous rock. "The necessity of safeguarding the lives of these men must be recognized before it is too late." No recommendation, however, is made as to the need for any periodic medical examination. As a contrast it is refreshing to read of what has been done under the inspiration of Dr. Charles Badham, the young medical officer of industrial hygiene in Sydney, in ventilating the underground workings through sandstone containing 86 to 95 per cent. of insoluble silica.[2] All shafts, drives, and adits are now rigged out with exhaust pipes along the sides of the shaft. The exhaust is produced by a compressed-air ejector situated in the centre of the pipe and near the outlet end. The compressed air is derived from the same source as that used for working the drills. Systematic sampling with the Owens dust counter controls the efficiency. In other cases—as, for example, tunnelling for the electric railway—ventilation is through holes in the roof, spaced at about 16 ft., each connected up to an exhaust fan. Dr. Badham is altogether satisfied with the results obtained with the Owens dust counter; from comparison made with commonly used methods of gravimetric sampling he comes to a most helpful conclusion that correlation between them exists, so that one milligram of quartz or sandstone dust per cubic metre is equivalent to 100 particles of less than 10 microns per c.cm. The average dust exposure of men using axial water-fed drills works out at 110 particles per c.cm. The Sydney sandstone mason, on the other hand, is exposed to an average of 4.2 milligrams, or 420 particles per c.cm. Important developments in simplification of methods of dust determinations should follow from this piece of work. In the New York report neither the Owens dust counter nor the Kotzé konimeter is even mentioned. All through these diverse reports on effects of dust we are confused by the different methods, not only of determining the dust content, but also of describing the results; and it is the same in the account given of the radiological findings as to the stage the silicotic condition has reached. The New York report accepts Pancoast and Pendergrass's classification into four stages—an ante-primary, a first, second, and third stage. Much space is taken up in showing how neither of the first two of these is apparently comprised within the South African classification into ante-primary, primary, and secondary. The Medical Board under the Refractories Industries in Great Britain uses the scientific formula of first, second, and third. "Ante-primary" sounds almost like a contradiction in terms. All these complications ought to be put right at the Johannesburg conference on silicosis next year. In his second paper Dr. Badham describes a case of rapidly fatal silicatosis from inhalation of orthoclase basalt dust containing no free silica. He refers to the very similar fine fibrosis found among the Broken Hill miners, where the dust contained less than 10 per cent. of quartz, but much silicate of iron and manganese. Finally, Dr. Irving Clark,[3] medical officer of the Norton Company, Worcester, Mass., manufacturers of artificial grindstones, from a review of the radiological examination of 137 men exposed to large doses of dust over periods varying from 10 to 41 years, concludes that continued inhalation of artificial abrasive dust composed of aluminium oxide or silicon carbide will not produce *disabling* silicosis in the working period studied.

THE GUARDIANS COMMITTEES.

THE Ministry of Health has now issued a further memorandum in connexion with the Local Government Act, 1929, dealing with the areas into which administrative counties should be divided for the purpose of forming Guardians Committees. The financial consequences of the Act should not be confused with the administrative consequences in this matter. The widening of the areas for the purpose of Poor Law finance is finally accomplished by the Act itself. The financial charges will in future be borne by the county as a whole. The main administrative responsibility also will be with the county council and such of its own committees as it chooses to use, but the very large function of arranging and supervising out-relief will, under the general authority of the Public Assistance Committee, be performed by local Guardians Committees for suitable areas within the county. A large number of county councils are exercised as to the formation of these areas. Some of them have indicated that they propose to retain the old Poor Law union areas. The Minister, however, points out that this is inadvisable. Such areas were originally formed about the year 1834, upon consideration of the means of travel then available. The railway and the motor car have long since made much larger areas both possible and convenient, and an adjustment is greatly overdue. It is better to make such adjustment now, when the functions of a Guardians Committee will necessarily be much less comprehensive than those of an old board of guardians (since many of these functions will pass to the Public Assistance Committee itself), and at a time when the major change is being made, rather than to postpone it till the further survey of the county districts prescribed by the Act for other purposes is made. There can be no doubt as to the wisdom of this advice; at the same time, the administrative schemes should be carefully scrutinized in this particular, for there may be a tendency for the areas now being determined for the purposes of out-relief being subsequently adopted for other public health purposes for which they might not be equally appropriate. It will be remembered that the Act lays down that the Guardians Committees should be composed partly of the county councillors elected for the area, partly of district councillors elected by the district councils comprising the area, and partly of suitable co-optative members. Their main function will, as has been said, be the direction of out-relief, but other functions may be assigned to them, in accordance with the Act, by the Public Assistance Committee. Amongst these is the duty of inspecting, visiting, and managing transferred hospitals or institutions situated

in their area. It is much to be hoped that the actual management of such hospitals will be reserved by the county council to its Public Assistance or Public Health Committee (preferably the latter), and that nothing beyond perhaps powers of visitation will be given to the local bodies. It is gratifying to note that in the present official memorandum this is the advice given to county councils by the Minister.

INSTITUTES OF RADIOLOGY AND RADIUM THERAPY.

THE twelfth set of papers on *Methods and Problems of Medical Education*,[1] brought out since 1924 by the Division of Medical Education of the Rockefeller Foundation, has now been published. This, the most voluminous of a valuable series, is entirely devoted to descriptions, written by the professors and directors in charge, of departments and institutes of radiology and radium therapy. There are thus brought together reports from 38 departments in eleven different countries; the United States heads the list with 13 reports, followed by Germany with 6, and Great Britain and France with 5 reports each. The first article, on radiology in practice, research, and teaching, and on the training of the medical radiologist, by Professor Holzknecht of Vienna, was published elsewhere last year and is now translated into English. This discusses methods of teaching and the period in the clinical course (whether at the beginning or the end) when instruction should be given, and the conclusion is reached that teaching and research must proceed independently. The second article, also a general one, on the organization and equipment of an *x*-ray department, by Dr. A. E. Barclay, formerly of Manchester and now lecturer in radiology in the University of Cambridge, is based on a paper read before the Röntgen Society in 1923: it contains a great deal of valuable detailed information. In dealing at some length with the important subject of protection Dr. Barclay expresses his own views, which in certain respects are at variance with those held by some members of the X-Ray and Radium Protection Committee. Professor Pancoast of Philadelphia writes on the problems concerned in planning radiological laboratories, and in his elaborate account of the departments of radio-physiology and medicine in the Radium Institute of Paris the director, Professor C. Regaud of the Pasteur Institute, deals with questions of organization and equipment, and after discussing whether or not an institution devoted to the radiotherapy of malignant new growths is worth while, decides that such efforts will be largely repaid in the future. Dr. Axel Reyn's account of the Finsen Medical Light Institute at Copenhagen is particularly well illustrated, and traces its evolution from small beginnings in a wooden building. The London radiological departments described are those of the Cancer Hospital, by the late Dr. Robert Knox, who sent his account in November, 1927, and of Guy's Hospital by Mr. J. M. Redding, who records the teaching given in the department —a routine course of ten lectures in the winter session and informal demonstrations, for which there is always plenty of material available. The *x*-ray department of the Royal Infirmary, Liverpool, is described by Mr. Thurstan Holland and Dr. Roberts, and the new radiological department of the Edinburgh Royal Infirmary, opened in October, 1926, by Dr. J. M. Woodburn Morison. The arrangements at several institutions for the treatment of cancer in Paris, Belgium, and elsewhere are set out, Professor Henri Hartmann providing the account of the surgical clinic at the Hôtel-Dieu, Paris. Space forbids even a mention of the other centres described, but everyone practically interested in the organization of a radiological department should be in possession of this volume.

THE PREVENTION OF MENTAL DEFICIENCY.

AT the end of our leading article in the *Journal* of July 20th last (p. 108), we said that "as the whole question of the causation of mental deficiency and its relationship to other abnormal mental conditions and social problems is at present difficult and obscure, the demand that a Royal Commission or other suitable official committee should be appointed to make full investigation of the subject is worthy of support." This demand is reinforced by a powerful letter, printed in the *Times* last week, from the Central Association for Mental Welfare, and signed, amongst others, by Sir Leslie Scott, the president, Miss Evelyn Fox, the honorary secretary, and by Drs. H. B. Brackenbury, Letitia Fairfield, F. E. Fremantle, F. C. Shrubsall, A. F. Tredgold, and F. Douglas Turner, who are all officers of that association. The letter points out, what we have ourselves drawn attention to, that the recent report of the Joint Mental Deficiency Committee proves that the problem is much more serious and pressing than has hitherto been thought. The number of mental defectives in England and Wales is increasing, both actually and relatively to the total population. Those who are socially as well as intellectually defective become a very heavy economic burden on the community in any event, but this burden is demonstrably much heavier if they are neglected than if they are cared for. For them all special training and social supervision are equally necessary complementary factors, and can be fully justified on grounds both of finance and of humanity. The prevention of the condition is a much more difficult problem. Mentally defective persons tend to produce mentally deficient offspring in relative abundance; but the vast majority of mentally defective children are not the offspring of mentally deficient parents. This makes inquiry difficult and systematic sterilization futile as a preventive measure. The council of the Central Association say in their letter, quite truly: "The segregation in institutions of defectives who are likely to propagate offspring and the prohibition of the marriage of defectives would have some preventive effect," by diminishing in small degree that proportion of defectives who derive from defective parents. These measures should therefore obviously be adopted without delay. "But," it is added, "before any preventive measures of real value can be taken, it is essential to have complete and accurate data regarding the many factors concerned in causation." A good deal of knowledge of the ancestry and family history of mentally defective persons is now available, and some experience of the genetic factors which lead to the condition in a number of cases is gradually being acquired. Along with this, demands for premature and drastic action are being made, based usually upon theories of the origin of the condition which are now quite untenable or very incomplete. Some authoritative inquiry and pronouncement is therefore needed, and even if such inquiry and pronouncement should ultimately prove to be inconclusive, it will not have failed in usefulness. Results of more positive value might, however, well be attained. It is to be hoped that action in the direction indicated will soon be taken by the Government.

THE council of the Canadian Medical Association has determined to establish a Blackader lectureship in diseases of children as a tangible expression of its appreciation of the services rendered by Dr. A. D. Blackader, who has just resigned the editorship of the *Canadian Medical Association Journal*, and as a mark of recognition of his eighty-second birthday. It was agreed that 5,000 dollars should be collected to endow the proposed lectureship, which will commemorate the pioneer and long-lasting interest taken by Dr. Blackader in the field of disease in childhood. The income of this capital will be applied once in every three years to provide an honorarium for the paediatrician chosen to deliver the lecture.

RADIOTHERAPY OF UTERINE CANCER.

THE RADIOLOGICAL SUBCOMMISSION'S REPORT.

THE Health Section of the League of Nations has just issued a valuable report from its Cancer Commission (of which Sir George Buchanan is chairman) on the subject of radiotherapy in cancer of the uterus.[1] This document of 82 pages takes the form of a general review of the work undertaken by the expert Radiological Subcommission which has been dealing specially with methods and results of radium and *x*-ray therapy in this region, together with reports on the technique and results of treatment in three large Continental centres—namely, the Radiumhemmet at Stockholm, by Dr. J. Heyman, chief of the gynaecological department; the Radiological Section of the University Gynaecological Clinic at Munich, by Professor F. Voltz; and the Radium Institute at Paris, by Dr. A. Lacassagne, assistant director of the Pasteur Laboratory.

An account of the preliminary meetings at Geneva of the Radiological Subcommission appeared in our issue of July 7th, 1928 (*p.* 21). At the first session its chairman (Professor Claude Regaud, director of the Radiophysiology Laboratory and of the Medical Department of the Radium Institute, University of Paris) undertook to prepare a statement of the principles which should now be accepted, on the basis of experience, in order to secure that radiotherapeutic treatment of uterine cancer is organized on the most effective lines, and that any dangers that have been demonstrated are avoided as far as possible. This statement forms Chapter VI of the subcommission's report, and is headed "Memorandum on the organization of, and the conditions required for, an effective campaign against cancer of the uterus."

Professor Regaud's Memorandum.

Professor Regaud deals first with factors which delay the diagnosis of cancer of the uterus and the means for promoting early diagnosis—namely, by propaganda among doctors and midwives and improvement of their gynaecological education, and by the general recommendation of a periodical examination for all women who have borne one or more children. For the latter purpose, he says, well-staffed and well-equipped clinics for gynaecological consultation would be required in every town, having direct liaison with micropathological laboratories in large centres. Whereas consultation centres for the detection of cases of uterine cancer should be numerous and easily accessible to all women of a district, Professor Regaud maintains that treatment centres should be few in number. This argument is developed in the next section on "appropriate treatment," which he defines as that treatment which at any given time corresponds to the level of progress reached by medicine. Unfortunately, in the treatment of cancer of the uterus medicine has not reached a condition of stability.

"As regards operable cancer of the cervix, surgical removal and radio-therapeutic methods both find ardent supporters. When the stage of operability is passed, the proportion of cures, or temporary improvement, stated to have been obtained by different experts is very unequal. 'Appropriate treatment' of uterine cancer is thus interpreted and put into practice in very different ways. It is clear that these divergences are attributable to the diversity and the inequality of the technique employed, and that the truth can only be established by a bureau of statistics which are above suspicion."

Apart from questions of technique properly so called, a considerable number of biological problems remain to be solved as regards the radiotherapy of cancer in general. Thus, as far as radiotherapy is concerned, whatever may be said for surgery, the last stage of progress is not nearly reached.

Professor Regaud then discusses the difficulties in the way of organizing radiotherapy, paying particular attention to the danger that arises from the increasing use of radium by practitioners insufficiently trained to its use.

"One of the most detrimental forms of this danger lies in the possibility for any doctor to hire radium, and, in certain countries, radium emanations, in the same way that he might order some surgical material or a drug. Information is usually furnished to doctors on the use of the radio-active material which they obtain by hire, but this consultation by correspondence is inadequate for the carrying out of appropriate treatment."

He develops this line of thought, indicating the harm that may ensue at different stages of the disease, from the propagation of radio-therapeutic methods among doctors and establishments having only a mediocre experience or insufficient material at their disposal. His conclusion is that the treatment of cancer of the uterus should be concentrated in a small number of institutions completely and perfectly equipped in every respect, these large centres being in close liaison with gynaecological and surgical clinics acting as subcentres. He recognizes the great difficulty in recommending limitation of the right of doctors to use radiotherapy in the treatment of cancer, but insists that the danger of widespread and uncontrolled employment of this method should be made plain to all.

So long as methods of technique are not standardized and divergent opinions exist among eminent surgeons on the subject, dogmatism would be premature. At the same time certain warnings are agreed to be necessary. In particular, doctors and the public should be put on their guard against the use of insufficient quantities of radium—a few needles, one or two tubes—with which it is well known that doctors of small clinics attempt to treat their patients. Abuse of *x* rays is less actively harmful than abuse of radium, but "it is well to insist on the difficulty of providing a deep pelvic irradiation which is at the same time both effective and not injurious; on the strength which machines and tubes ought to have; on the particularly laborious character of efficacious treatment; on the obligation resting on doctors not to allow, in their absence, the direction of the anatomo-topographical and physical requirements of the radiation treatment to pass out of their hands into those of mere manipulators."

Rules for Compilation of Statistics.

No less important than Professor Regaud's memorandum is Chapter II, which has been based on preliminary proposals put forward by Dr. Heyman, Dr. Lacassagne, and Professor Voltz. This embodies a set of rules adopted by the subcommission with the object of establishing a basis for full and comparable statistics of radiotherapy for utero-vaginal cancer. These rules might with advantage be displayed in every place where this treatment is given. The classification of the different varieties and stages of cancer of the cervix appears to be thoroughly sound; while for purposes of comparison it is clearly essential to have full data relating to the technique of treatment as set out at page 17 of the report. Our only criticism is that there are no headings for entering these particulars on the model individual case record appended to the rules. This record card, indeed, scarcely seems quite adequate for the purpose in view. It may be intended to serve merely as an index card, but, even so, the headings seem insufficient, and some of the vacant spaces on the back might have been allocated for the entry of essential details of diagnosis and treatment, instead of crowding these on to the front of the card.

Reports from Three Radium Centres.

The three detailed accounts of methods and results at the clinics represented on the Radiological Subcommission—namely, the Radium Institutes of Stockholm and Paris, and the Frauenklinik of the University of Munich—comprise respectively Chapters III, IV, and V of the report. These are highly technical, and each is freely illustrated. The subcommission recognized that in order to appraise at the present time the potentialities of radium treatment in cancer of the uterus, it would be necessary to have resort only to a small number of institutes possessing lengthy experience of the subject, and that in assessing results only those cases should be taken as cured in which five years of survival after treatment had been proved. In the preparation of the reports of these clinics at Stockholm, Paris, and Munich, the subcommission arranged for co-operation through Dr. Tomanek, secretary of the Cancer Commission, so that a thorough study might be made of the results achieved at different stages of the disease.

[1] League of Nations Health Organization. Cancer Commission. Reports submitted by the Radiological Subcommission. June, 1929. [C.H. 783.] Geneva.

Originally it had been anticipated that this work of study and comparison would enable statistical data to be drawn up on the basis of which certain forms of radiotherapy—radium alone or combined with *x*-ray therapy—could be specified as giving the best proportion of cures. The methods employed in the three clinics differed, however, in so many essential particulars, that it was not possible to realize this anticipation. Each clinic, moreover, had a different conception of the definition of the various stages of uterine cancer, while the data regarding after-histories and survival were inconsistent. The material supplied to Dr. Janet Lane-Claypon (who acts as investigator for the subcommission) showed that the three clinics have not hitherto followed the same principles in classifying the forms and stages of carcinoma of the cervix, and that the methods of treatment over a number of years have varied considerably, not only as between the different clinics, but also in the same period. It was accordingly decided, after full consultation between those concerned, that the expert at each clinic should set out in his own way the details of the methods there followed, and the results obtained at the institution which he represented.

These three reports show very clearly the wide variety in the radio-therapeutic methods used at the three clinics in question. At Stockholm the internal use of radium only has been the chief method during the whole period dealt with (1913–23). In Munich, although the available data go as far back as at Stockholm, there have been notable variations in the methods of treatment used, which have led up to the present method of combined *x*-ray and radium therapy described by Professor Voltz in Chapter IV. The work of the Radium Institute in Paris (Fondation Curie) having commenced somewhat later, in 1919, the available sample is both numerically smaller and the results have been collected for a shorter period than at the other two clinics. On the other hand, the methods at the Fondation have undergone an almost continuous evolution with continuously improving results.

Much of the information contained in these chapters dealing with the work of the clinics in Stockholm, Munich, and Paris has already been published in some form or other, but further information is given here for the first time or in a new way, and its publication gives an opportunity for studying side by side the methods and results of these three important institutions.

General Considerations.

The subcommission, in concluding its introduction to the whole report, lays great stress on the importance of the general considerations formulated by Professor Regaud in Chapter VI, holding that the assertion of these principles is an important duty. They represent conclusions which the members of the subcommission as a whole (Professor Regaud, Mr. Comyns Berkeley, Professor A. Doederlein, Dr. Heyman, Professor Lahm, Professor Pestalozza, and Professor Van Rooy, with Sir George Buchanan, *ex officio*) have been able to accept unanimously. The members are all agreed as to the necessity for promoting earlier diagnosis of cancer of the uterus, and the consequent greater facility of cure by radiological methods. Propaganda with this end in view is needed in every country, and not least in Great Britain.

Reviewing the report as a whole, and the three special monographs it contains, it becomes apparent that when the results therein shown are compared with those obtained only a little earlier, even by the most skilled surgical treatment, the position already reached by radiotherapy in cancer of the cervix uteri is highly encouraging. At a time when radium is being used more than ever before, the kind of information given in this report should be invaluable. Without its guidance medical men coming to radium treatment fresh and with enthusiasm will be tempted to waste time and possibly cause loss of life by following lines of procedure which foreign expert experience has already conclusively shown to be unprofitable. Moreover, the standard classification of stages of cervical carcinoma and of the data required for the comparison of statistics should prove of great advantage to all clinics and hospitals, and to those who undertake a similar inquiry in the future.

Scotland.

Report of the Scottish Board of Health.

The tenth annual report of the Scottish Board of Health, dealing with the year 1928, was issued in April last, and reference was made to it in our columns on April 20th (p. 740). The functions of this Board have now been taken over by the Department of Health for Scotland, and the report, therefore, dealt at some length with the more important developments in public health matters in Scotland which had occurred during the ten years of its existence. Certain sections of it have now been reprinted; these comprise the work of the district medical officers under the National Health Insurance Act; hospital planning and construction; medical service in the Highlands and Islands; milk and the school child; and mortality and sickness associated with pregnancy and parturition. These reprints may be purchased directly from H.M. Stationery Office, each of the first three named at the price of 6d. net, the fourth at 4d., and the fifth at 3d. The important information which was contained in this report is therefore made available now in convenient form for all interested.

Summer Graduations at Edinburgh University.

At a graduation ceremony, on June 28th, eighteen honorary graduands were capped and more than four hundred other non-medical degrees and diplomas were conferred. Among the honorary graduates were Dr. Albert Schweitzer, medical missionary in West Africa, who had the unusual distinction of receiving two honorary degrees at the one time, those of Doctor of Divinity and Doctor of Music; Edward Stephen Goodrich, D.Sc., F.R.S., professor of zoology, University of Oxford; Archibald Vivian Hill, Sc.D., F.R.S., Foulerton Research Professor, Royal Society; and Sir James Walker, D.Sc., F.R.S., professor emeritus of chemistry, University of Edinburgh. Miss Sybil Thorndike, the distinguished actress, who received the honorary degree of Doctor of Laws, had a particularly cordial reception. On July 17th, at the medical graduation, twenty M.D. and ninety-five M.B., Ch.B. degrees were conferred, thirteen of the latter upon women. James Laurie, Scotland, was the most distinguished male graduate, gaining the Ettles Scholarship, and Agnes Yewande Savage, West Africa, the most distinguished woman graduate, receiving the Dorothy Gilfillan Memorial Prize. It was announced that the Cameron Prize in therapeutics had been awarded to Lieut.-Colonel Sir Leonard Rogers, C.I.E., M.D., F.R.S., in recognition of the discoveries he had made in the treatment of tropical diseases, in particular of cholera, amoebic dysentery, and leprosy. Professor T. J. Mackie, M.D., of the chair of bacteriology, in the course of an address to the new graduates, said that the last twenty-five years had witnessed radical changes in medicine, and it was open to doubt whether medical education had adapted itself properly to the new orientation. Some educationists seemed to regard a medical training as lacking in general culture, but in reality it was a liberal education. Much, of course, depended on the seeds of general education that had been sown during the school years. Variation in that educational "substrate" was enormous, and their statutory minimum of general education was probably not sufficient on which to build the philosophic and scientific training which the ideal medical education should consist of. The outstanding faults of their medical educational system at the present time were the products of its growth and evolution, and the time had perhaps come when it should undergo a radical reconstruction. The trend of practical medicine had been towards scientific application, and the most thorough science training was now indispensable in medical education. Apart from the knowledge it conferred, there were habits of mind it created, and a technique of work it instigated, which were essential if medicine was to maintain a high standard of rationality immune from all encroachments of quackery and empiricism. It was all-important that at the very threshold of university study there should be a broad introduction to general biology—not botany or zoology as such, but the science of life in its broadest aspects—leading up to the more specialized study of the biology of the human species.

The physical sciences also lay at the very foundation of medicine. Anatomy and physiology, with biology, physics, and chemistry, made up the complete basic structure of their educational edifice. The closest co-ordination of these preliminary studies was necessary, and probably still more could be effected in this direction. When the student passed on to the applied biology of practical medicine he had to pass through the hands of an increasingly large number of specialists, and at this stage of the curriculum there was an even greater danger of overlapping and lack of proportion. Different departments of medicine could join in a co-ordinated plan of teaching and still maintain their identity and express their individuality. The further question arose whether the existing system of examinations in subjects might be replaced by yearly examinations corresponding to annual units of instruction. Professor Mackie had no sympathy with the view that the scientific attitude was almost incompatible with practicality, and that their duty was to teach the medical student the so-called art of medicine by bedside training according to thoroughly practical tenets, leaving scientific medicine as a thing apart in the research laboratories. If medical training were stripped of its scientific instruction it would hardly justify a university degree, and would be degraded to a mere apprenticeship. Again, it was often lamented that in certain of the medical schools clinical training was inadequate, and that the student did not see and personally handle a sufficient amount of so-called clinical material. But how could any undergraduate training give real experience? Several years of responsible medical work was required for that, and responsibility began only after graduation. Other matters touched upon by Professor Mackie were the feasibility of having an Honours Degree in Medicine on the analogy of honours degrees in other faculties, and the desirability of reducing the output of doctors by selecting a limited number of pupils. After wishing the new graduates success in their life's work in the name of the University, Professor Mackie paid a warm tribute to the principal, who was that day presiding over his last graduation ceremony, and Sir Alfred Ewing feelingly replied.

Gift to Edinburgh University.

Mr. Thomas Cowan, LL.D., has given a further sum of £20,000 to Edinburgh University to be held in trust as a fund, out of the revenue of which grants may be made, in the form of scholarships or otherwise, to promote the entry of thoroughly well-qualified students to Cowan House (see *British Medical Journal*, June 15th, p. 1097). Mr. Cowan desires that the residence should attract young men who, in respect of intellectual force or other personal characteristics, are likely to have a useful influence on their fellow students and to become a credit to the University, and he is anxious that no such student should be debarred from taking up residence because of monetary considerations. Mr. Cowan's gifts to the University, mainly in connexion with the residential hall which bears his name, now total £35,000.

Extension of Edinburgh University Settlement.

Tucked away in a corner off Infirmary Street, Edinburgh, are the remains of the old High School, of the former Infirmary buildings, and of the anatomical room connected with Burke and Hare. The anatomical room is now the billiard room of the Edinburgh University Settlement, a new annexe to which was opened by Lady Ewing on July 17th. This is a hall which has been erected on ground loaned by the University Court, and which will eventually be used in a variety of ways related to the objects of the Settlement, which are to supply social and educational facilities to residents in the Cowgate district. In the meantime, it is to be used as a toddlers' playground, and as an occupation centre for mentally backward children.

Peerage for Sir James Mackenzie's Brother.

The announcement on July 11th that the King had been pleased to approve that the dignity of a barony of the United Kingdom be conferred upon Sir William Warrender Mackenzie, G.B.E., K.C., is of interest to the medical profession because of the fact that the new peer's brother was the late Sir James Mackenzie of Burnley, London, and St. Andrews. Sir William Mackenzie was educated at Perth Academy, Edinburgh University, and University College, London, and was called to the Bar at Lincoln's Inn in 1886. After practising on the northern circuit, and publishing several well-known works on local government and the licensing laws, he was appointed, in 1917, chairman of commissions on industrial unrest in the Manchester and the south-west district. Since that date it has fallen to his lot to sign hundreds of awards adjudicating highly technical problems and conciliating great numbers of men. His colleagues testify to his effective methods of tackling difficult and long-standing labour troubles, and to his ways of appeasing and reconciling long-estranged sections of capital and labour in the public interest. Sir William was chairman of the British Government industrial delegation to Canada and the United States, 1926-27.

England and Wales.

Central Midwives Board.

The Central Midwives Board for England and Wales met on July 18th. The Standing Committee considered a letter from the medical officer of health for the County of London, stating that the Midwives Act Committee desired the Board's views on certain points submitted:

(1) Is it obligatory upon a midwife to examine a patient herself, even if the patient is referred by the midwife to an ante-natal clinic, provided the midwife assures herself that the patient is in fact attending such clinic?

(2) Must the midwife keep ante-natal notes of the patient in the above circumstances?

(3) If so, is it sufficient if the midwife enters as her ante-natal notes any information conveyed to her from the ante-natal clinic?

The Board's replies were:

(1) If a midwife does not make the necessary ante-natal examination of her patient, she must see that the patient attends an ante-natal clinic and undergoes such examination.

(2) Ante-natal notes must, in any event, be kept by the midwife, but she can, in preparing such notes, make use of the information conveyed by the ante-natal clinic.

(3) It is, of course, highly desirable that a midwife should herself ascertain the condition of any patient whose confinement she will undertake.

A letter was read from the clerk of the county council of the West Riding of Yorkshire, on behalf of its Child Welfare Committee, asking the Board to take into consideration the question of changing the description of "midwife" to that of "certified maternity nurse," as being a more suitable description, and to take steps in that direction. It was agreed to reply that the word "midwife" is of extreme antiquity and of unambiguous meaning: the term "certified maternity nurse" has neither of these points in its favour, and the Board cannot entertain the suggestion made.

An Ambulance for Liverpool Hospitals.

An ambulance presented to the Merseyside Hospitals Council by the Guild of Undergraduates of the University of Liverpool is claimed to be the most luxurious in the country. It will help to meet an urgent need in the city, where at present there is no organized system of motor transport to serve the sixteen voluntary hospitals. The Merseyside Hospitals Council has introduced a scheme of regular weekly contributions to voluntary hospitals, and already 200,000 employees contribute one penny in each £ of their wages, to which employers add one-third of their employees' contributions. This scheme produces £100,000 per annum for the local voluntary hospitals, and no less than £63,000 has been collected already this year. The ambulance, which was purchased out of part of the money collected by the students at their annual "rag," will assist to provide transport for members of this wide circle of regular contributors and their families, the unemployed, and other necessitous persons. It is a 35/120 h.p. Daimler long chassis model, the interior being equipped with all the latest appliances, including revolving seats which can be converted for stretcher or sitting patients. Rubber cushions are provided on both stretchers, and the seats are also padded with sorbo rubber with leather covers. By

means of the revolving ratchet system the ambulance can be used for ten sitting patients, or two stretcher patients, or five sitting patients and one stretcher case. The stretchers are fitted with adjustable back rests where it is necessary for the patient to be in a reclining or partially sitting position. A hot-water tank fed from the silencer heats the ambulance, and also supplies a nickel-plated collapsible wash-bowl. A first-aid cabinet has been fitted, and there is a folding seat for the use of an attendant. A fully qualified attendant and driver will always accompany the vehicle. Specially illuminated canopy signs have been fitted at the front and rear in order that the vehicle may be recognized as an ambulance at night on the country roads, and a Winkworth bell will give a distinctive warning note. The wings and wheels are painted red and the bonnet and body a deep cream, bearing the words, in gold lettering, "1d. in the £ Fund." It is expected that the Merseyside Hospitals Council will soon add further vehicles of a similar kind to cope with the urgent problem of transport to and from the voluntary hospitals.

Local After-effects of Radium Treatment.

Valuable observations on the local after-effects of radium treatment are recorded in the sixth annual report of the Harker-Smith registrar (Dr. N. Asherson), who deals with all cases treated by means of this agent from November 1st, 1927, to October 31st, 1928, in the Obstetric Unit of University College Hospital, London. He states that certain late local sequels, not previously noted, followed the application to the pelvic organs of larger doses of radium than have hitherto been employed. In the treatment of non-malignant conditions the slipping out of the tube from the uterus into the vagina has resulted in the production of radium burn of the vagina. To prevent this accident a plug of gauze was inserted into the cervix, fixing the tube to its lip; adequate screening of the radium with a tube of platinum (walls 0.5 mm. thick) encased in a rubber tube 2 mm. thick, by cutting out the alpha and beta rays, has also proved effective to the same end. Atrophy of the whole of the vaginal portion of the cervix, leaving the external os flush with the vaginal wall, has occurred after the application of a dose of 2,500 mg.-hours. Other sequels observed to follow the treatment of non-malignant conditions have been vaginitis, shortening and stenosis of the vagina, annular constriction of the vagina, and ovarian neuralgia. The vaginitis has been both purulent and adhesive, the former being associated with profuse discharge which, though chronic, ultimately ceases, after causing flimsy adhesions between the anterior and posterior vaginal walls. Shortening and stenosis of the vagina has been a not uncommon result of exposure to doses larger than 3,000 mg.-hours of element. Where it has developed, the examining finger, within two months of the treatment, could be admitted for about 1 inch only, the rest of the canal being cicatrized in all directions. The mucous membrane was intact, and there was no ulceration or bleeding. The changes have occurred in the submucous tissues, and are apparently fibrotic in nature. Two cases of annular constriction were noted during the year, both being associated with complete atrophy of the vaginal portion of the cervix; in one the dose was 4,200 mg.-hours, in the other 4,000 mg.-hours of element. The constriction has appeared as a fibrous linear ring, about 1 inch from the introitus; it has been found to yield to firm pressure, the vagina, proximal and distal to it, being normal. In neither of the cases was there any ulceration. Only one case of ovarian neuralgia was noted. The patient was a woman, aged 51, with menopausal haemorrhage, who after treatment with 2,500 mg.-hours of element, complained of neuralgia over both ovarian regions extending down the inner side of each thigh to near the knee. It is stated in the report that in no instance has malignant disease supervened in a uterus which has been subjected to radium treatment for menopausal or any other kind of menorrhagia; nor has pyometra been noted in the non-malignant series. In cases of malignant disease analysis of the after-effects of radium is complicated by the fact that it is impossible to differentiate between the normal ravages of the disease itself and the lesions produced by the treatment. In previous reports the following conditions have been recorded: persistent pyrexia, pyometra, pelvic abscess, pelvic peritonitis, fistulation, and dissemination of growth. In the present report attention is drawn to two cases in which stenosis and shortening of the vagina occurred. In one, an application of 8,530 mg.-hours of element was followed in six weeks by complete atrophy of the cervix, with shortening of the vagina; in the other, the application of 10,000 mg.-hours of element was followed in five months by marked vaginal shortening.

Correspondence.

MATERNAL MORTALITY.

SIR,—Dr. Watts Eden's article on the national inquiry into the causes of our high maternal mortality rate (*Journal*, July 20th, p. 81) should be welcomed as a well-balanced and unbiased critical survey of evidence which has recently emerged in the course of inquiry into the factors influencing maternal mortality, and particularly that due to puerperal sepsis.

In dealing with the Aberdeen report on maternal mortality, Dr. Eden points out that the influence of the general health of the mother is a matter on which very little information has been available in the past; yet it is now recognized that its true significance is a matter requiring the fullest investigation in the future. So far as the "droplet" infection theory is concerned, this is, of course, largely hypothetical, but assuming the haemolytic streptococcus can be conveyed by droplet infection to the genital canal, is it not reasonable to suppose that puerperal sepsis would be of much more frequent occurrence than it is?

When Dr. Eden touches on the importance of providing proper means of isolating septic cases, he must surely carry the weight of experienced obstetric opinion with him when he says that an isolation block is a *sine qua non* of every properly equipped maternity hospital. I do not think that any maternity hospital can be regarded as safe, much less ideal, unless it provides for the treatment of septic cases arising within its walls, in a block which forms a separate building and has a separate staff, where segregation is absolute. It is therefore gratifying to know that Queen Charlotte's Hospital has taken a lead in this direction, for such provision is not, as has been stated by some, to be regarded as a relic of the past, but, on the contrary, is an essential of the future. There is abundant evidence that once a virulent streptococcus invades a maternity ward, which may happen to be overcrowded, the rapidity of infection may be so intense that neither aseptic nor antiseptic measures will be able to cope with the spread of infection.

There is only one way in which the study of puerperal sepsis is likely to be followed by fruitful results, and that is by a much closer co-operation between the obstetrician, bacteriologist, and public health authority than has existed in the past. One of the greatest advantages in having isolation provision for a certain number of cases at the maternity hospital is the giving of clinical instruction to the medical student and midwife by the obstetrician. This, which should be a strong feature in our teaching, is unfortunately often the weakest, and it is therefore not surprising to find many cases of puerperal sepsis unrecognized as such by the young practitioner.

Lastly, the Aberdeen report endorses the view that the development of a new midwifery organization in which midwives will conduct *all* normal deliveries, and in which doctors will only provide ante-natal services and deal with obstetrical complications, would result in a significant reduction in puerperal mortality. While I agree that there is great need for an improved maternity service based on a midwife-doctor combination, I very much doubt the wisdom of restricting the general practitioner's activities to complicated labour only, and dispensing with his services altogether in cases of normal labour. I venture to think that this would prove a retrograde step of considerable magnitude. This assuredly would lower the whole status of midwifery, and while it would be profoundly interesting to have the views of those engaged in general practice,

frankly I believe it would tend to a state of affairs which, as a teacher of midwifery, I shudder to contemplate.—I am, etc.,

University College, Dundee, July 23rd. JOHN MCGIBBON.

SCHOOL PREVENTIVE MEDICINE IN RURAL AREAS.

SIR,—As chief school medical officer of an agricultural county I read the article by Dr. A. C. T. Perkins in the *Journal* of July 20th (p. 95) with an interest which was enhanced as I found that the problems encountered in Suffolk resemble, in many respects, those which confront us in Dumfriesshire.

I need not detail the many points on which I heartily agree with Dr. Perkins, but turn rather to that on which I disagree, with equal cordiality. The abolition of rural schools and their replacement by large central institutions for at least 1,000 pupils would doubtless simplify medical inspection and after-care, and might, I admit, have other real advantages, but it would give the *coup de grâce* to what remains of the rural culture of these islands. This, I submit, would be not only a matter for sentimental regret, but a hygienic catastrophe. It is in the national interest that we should retain a strong and vigorous country life, and anything which might tend to increase rural depopulation is to be avoided. Not only is the country child generally superior physically to his town-bred fellow of the same age group, but the mentality induced by bucolic life, albeit somewhat lethargic, provides counterpoise to that of the urban intelligentsia and thus is not without its value in the national economy.

Dr. Perkins points out, very justly, that school occupies only a small part of a child's time, and that home conditions are of paramount importance. I fear that schools of the kind he proposes would develop an atmosphere so alien to that of the pupil's domestic environment that any influence they could exert on the home life of future generations of country dwellers would be very small. Inevitably pupils would leave them less attracted by the prospects and the "cultural accessories" of country life than by those of the town. But many of the public health problems which the nation has to face to-day are sequelae of the uncontrolled development of towns at the expense of the country during past generations. City life for the masses has become so strenuous and so specialized, so detached from tradition and, in consequence, so easily affected by the catchword of the moment, that the steadying influence of the countryside is almost essential to national sanity. So while the ambitious country lad, convinced that a clerk in an office lives more nobly than a rural blacksmith, sees his Mecca in the town, and the disillusioned townsman seeks tranquillity in the country, successive Governments, by "small holding" schemes, and social workers, through such agencies as rural institutes, are endeavouring to salvage something of the life and art which are in peril of disappearing in the clash of urban and rural cultures.

I admit that the medical supervision of a number of small and scattered schools is wasteful of time and temper, and that most country schemes are in need of improvement and development, but this is only one aspect of a much larger question. Rural hygiene can be made to justify itself, not by imitating that of towns, but by developing its own methods to suit its own needs. I think we must stop short, meantime, of Dr. Perkins's schools with their thousands of infant rusties, and inquire whether we cannot make the desired reforms without taking quite so long a step towards universal urbanization.—I am, etc.,

Dumfries, July 23rd. JOHN RITCHIE.

PHYSIOLOGY AND PHYSICO-CHEMICAL REACTIONS.

SIR,—The address on "Physiology the Basis of Treatment," by Professor W. E. Dixon (July 27th, p. 138), and your leading article on that address are obviously of great importance. But you head your article "The Neglect of Pharmacology," which seems to me a partial consideration of Professor Dixon's problem, which might be just as aptly entitled "The neglect of physiology."

"Physiology," writes Professor Dixon, "in the broad sense in which it was used by Claude Bernard and Huxley has given place to a new physiology of physico-chemical reactions: I might go beyond this and say that physiology is getting further and further from practical medicine, and this is the more regrettable as most of the chairs in physiology are connected with the medical schools and because the science of treatment is largely dependent on experimental physiology."

I am afraid many modern textbooks are apt to give the impression that there is arising a new physiology of physico-chemical reactions. But those whose hobby it is to follow in the tracks of investigators who glibly apply physico-chemical reactions to elucidate the working of the body, know that their triumphs have been very short-lived. For example, there is a monograph on the function of the kidney which might be called an example of "the new physiology of physico-chemical reactions." A few ugly facts discovered by physiologists in the *broad sense used* by Claude Bernard and Huxley have shattered the underlying theory of that work, but not its usefulness.

There is another work on the fluids of the body which might be called an example of the new physiology of physico-chemical reactions. Some more ugly facts discovered by physiologists in the broad sense used by Claude Bernard and Huxley have left very little of that excellent and most stimulating monograph standing.

There is ample room for both schools of physiologists, because the ill-equipped school is the school of exponents of physico-chemical reactions. Any schoolboy can take a physico-chemical law and apply it to phenomena in the body, but it requires physiology in the wider sense which embraces, or attempts to embrace, all data, whether physico-chemical or otherwise, to revise the application of physico-chemical law. But the real regret in Professor Dixon's mind is that those who apply exclusively physico-chemical laws are in many of the chairs of physiology in this country. A far greater danger to advance in physiology and in the treatment of disease lies in the extraordinary document I received from a university desirous of electing a new professor of physiology. It was an essential condition that a photograph of the applicant should be sent in with his application. Consequently I see signs that physiologists of the future must visit the beauty parlours, and, if this example spreads, physiologists will be chosen not because they are devotees of physico-chemical law or followers of Claude Bernard and Huxley, but because they can with credit compete with the leading man of a musical comedy.—I am, etc.,

Halesowen, July 27th. JAMES M. MCQUEEN.

A PHYSIOLOGICAL STUDY OF ASTHMA.

SIR,—The abstract of Brodie and Dixon's paper which you published lately (July 13th, p. 68) is a very valuable piece of work, but I would like to point out that though the writers say that "previous workers had established the fact that the motor nerve to the bronchial muscles was the vagus," yet in 1885 the late Professor Roy and Dr. Graham Brown discovered that the vagus contained fibres which caused expansion of the bronchi.[1] They employed a new method of experiment, and say that "section of one vagus usually causes a marked expansion of the bronchi of the corresponding lung," and that "frequently, and especially in non-curarized animals, narcotized with ether, stimulation of the central end of one cut vagus, the other being intact, causes a powerful expansion of the bronchi"; and "in these animals stimulation of one uncut nerve, the other being cut, causes often a marked expansion of the bronchi," etc. Such and other facts given indicate that "the vagi contain centripetal fibres which can cause both contraction and expansion." Discussion is given of the centres, direct or reflex, in the cerebro-spinal tissue, and of the drugs which can influence the bronchi, and they ask whether the brochial contractions are vermicular or rhythmic, which they have reason to believe they occasionally are.—I am, etc.,

London, W.1, July 24th. A. GUNN AULD.

[1] *Proc. Physiol. Soc.*, May 10th, 1885, p. 21.

THE DICK TEST IN PREGNANCY.

SIR,—Drs. Salmond and Turner, in their paper on the results of 533 pregnant women tested at the Royal Free Hospital (*Journal*, July 27th, p. 145), state:

"2. Of 158 Dick-positive reactors 20 per cent., and of 373 Dick-negative reactors 15 per cent., became febrile. . . .

"4. There was no significant difference between the liability of the Dick-positive and Dick-negative pregnant women to suffer from 'fever' in the puerperium."

Dick-positive reactors therefore suffered from febrile disturbances in a greater percentage than Dick-negative reactors, the difference being 5.0 ± 2.3 per cent. The ordinary statistical criterion of significance is a difference three times the probable error, which corresponds to a probability of 22.24 to 1 against the difference being purely a matter of chance.

In this case the difference is 2.2 times its probable error, corresponding to a probability of 6.25 to 1 against the difference being purely a matter of chance. This observation supports that of Burt-White, and the bald statement that the difference is not "significant" is a rather lame conclusion to an interesting piece of work. The accepted criterion of "significance"—that is, of adequacy of data for conclusions—is purely arbitrary. The results appear to have some significance, though the exact significance is not yet clear.—I am, etc.,

C. O. STALLYBRASS, M.D., D.P.H.,
July 29th. Assistant Medical Officer of Health, Liverpool.

GAS-OXYGEN ANAESTHESIA.

SIR,—I disagree entirely with Dr. E. J. Chambers's statement on July 13th (p. 74) that very few students have ever been taught gas-oxygen anaesthesia—at any rate in London. I agree that gas-oxygen is the least toxic form of anaesthesia, but in the course of my experience I have noticed: (1) That it is very difficult to obtain sufficient relaxation for emergency abdominal work. Personally I have almost always found it necessary to add ether in order to preserve peace with the surgeon. (2) That it appears to increase bleeding, even when very great care is taken to avoid cyanosis. These to me appear distinct drawbacks to its use as a routine anaesthetic, although I admit its value in specially selected cases.

Personally I have often found that in bad cases of intestinal obstruction it has been impossible to induce on gas-oxygen, while the patient goes quietly to sleep on a few drops of pure chloroform, followed either by open ether or by ether from a Shipway's apparatus. For general upper abdominal work I have been won over to endotracheal gas-oxygen-ether anaesthesia after ether induction.

Lastly, I entirely agree with Dr. de Lacy Walker's maxim (June 29th, p. 1180) that "routine anaesthesia is bad anaesthesia," and that each case must be judged on its merits.—I am, etc.,

ARTHUR L. MOORBY, M.R.C.S., L.R.C.P.,
Late Junior Honorary Anaesthetist, King's College Hospital.
H.M.S. *Sandhurst*, July 22nd.

CYST IN THIRD VENTRICLE OF THE BRAIN.

SIR,—I was extremely interested to read in the *British Medical Journal* of July 13th (p. 47) Professor Drennan's account of two cases of cyst in the third ventricle, and also the letters on the same subject on July 20th (p. 122) from Dr. Arthur Hall and Dr. Edwin Bramwell. A similar case occurred in my practice about six years ago.

The patient, an Australian business man, aged 36, was on a visit to this country, and called me in because of severe headache. He gave a history of headaches off and on all his life, stating that three years previously they had been very severe, with the result that he had a complete breakdown, and was advised to rest for three months; the headaches disappeared, and his health improved greatly. The condition was evidently considered to be migraine by his medical advisers.

On November 7th, 1923, I first saw him; the headache was obviously very severe; his complaint was of "throbbing in the temples" and of "waves beating inside his head." The pulse rate was normal, and there was no vomiting nor visual disturbance. I assumed it to be a case of migraine, and kept the patient in bed for a few days; during this period the headache was completely relieved at times, but returned at irregular intervals, though not so severely as on the first day. I was struck, however, by the patient's great apprehension of a return of his symptoms.

On November 12th, at 5 p.m., I received an urgent call, and found him very ill; the headache was agonizing; he had been sick, and was pale, sweating, and collapsed, with an irregular pulse of 36. I had him moved to a nursing home, having made a tentative diagnosis of cerebral tumour. He was given morphine, and slept at intervals during the night, but called out with pain frequently. In the early morning he gradually became comatose, and at 7 a.m. suddenly became cyanosed and died. A post-mortem examination was performed with the help of Mr. T. W. Letchworth. The brain then revealed a definite flattening of the convolutions; the lateral ventricles were markedly distended, and on opening into the third ventricle a small cystic tumour, about the size of a large currant, popped out. Unlike Professor Drennan's cases the cyst was not impacted, but was on a long pedicle, and appeared to have been acting as a ball-valve over the opening of the aqueduct of Sylvius, thus accounting for the periodical headaches. The cyst was connected with the choroid plexus of the ventricle, and was reported by Professor L. S. Dudgeon to be haemangiomatous in nature.

—I am, etc.,

Surbiton, July 27th. A. R. C. DOORLY.

PRURITUS ANI.

SIR,—Within the last few weeks you have printed considerable correspondence on the subject of a very common, distressing, and persistent complaint—pruritus ani. Many are its causes and many the suggestions that have been offered in the way of treatment, but I have failed to notice one very simple and often effectual way of dealing with this troublesome affection: that of ablution of the anus and surrounding parts with cold water after defaecation, and gently drying the skin with some soft material. By such easy means the parts are perfectly cleansed, and the frictional effect of using paper is removed. One of the most resistant and intractable cases I ever encountered, one which had resisted almost all known methods of treatment—oils, ointments, sedative lotions, soothing suppositories, and injections—responded rapidly and completely to this simple plan of anal toilet.

So impressed am I with the fact that very many of these cases are the result of irritation of the skin, first evoked by the faeces, and added to by the frictional rubbing necessary in the use of paper, that Messrs Shanks, the Scottish sanitary engineers, have, at my suggestion, devised and placed on the market a closet termed "bidet," that enables the easy toilet of perineal ablution after each movement of the bowels. I have ventured to suggest, after a very long hospital experience, that no institution of the kind should be without the installation of one or more of these "bidets." The simple method of ablution should, at least, be employed as an initial procedure in all cases, whatever may be the primary cause of the complaint.—*I am, etc.*,

Peebles, July 19th. A. ERNEST MAYLARD.

THE RELATION BETWEEN MUNICIPAL AND VOLUNTARY HOSPITALS.

SIR,—I am not surprised at the vigorous protest called forth by my letter in your issue of July 6th (p. 33) from the medical officer of a Poor Law infirmary, and a member of the staff of a large municipal general hospital, run on the same lines as a large voluntary general hospital in a great city—the only municipal hospital run on these lines, I believe, in this country. But I have expressed no desire to "degrade" the Poor Law or municipal hospitals; indeed, the present municipal hospitals, with the exception of the one at Bradford, only admit infectious and tuberculous cases, and I did not refer to them in my letter. I expressed the view that the transferred Poor Law hospitals should continue to work on exactly the same lines as they do now, except that cases requiring major operations should be treated at the large voluntary city hospital; and neither I, nor so far as I know anyone else, is "indignant" at

any improvement in their standard of work. What I do think is that they are doing a very necessary work, and should, when transferred to city councils, continue that work—for it must be done—and leave the voluntary hospitals to carry on the work for which they are better suited than the Poor Law hospitals. Mr. Holroyd Slater (July 20th, p. 126) calls attention to the hospital at Bradford as an example of what the transferred Poor Law hospitals should become. But the circumstances connected with the origin of this Bradford Municipal Hospital were altogether exceptional. The Poor Law Infirmary was municipalized ten years ago, for at that time the majority of the members of the city council were socialists, and they thought Bradford ought to have a municipal hospital. The large voluntary hospital of the city was too small, but a new site for it had been acquired, and attempts were made to raise the £200,000 required for its rebuilding. This was during the war, and, as might have been expected at that time, was unsuccessful. At this juncture the corporation started its scheme of the municipal hospital as a rival to the voluntary one. (See *Journal*, 1920, vol. ii, pp. 527, 552, and 753.)

If the voluntary hospitals do not receive adequate support from the charitable public, then we must have municipal hospitals to replace them, or the municipality must finance and control the hospitals now supported by voluntary effort; but once rate-supported hospitals, of equal efficiency to the voluntary ones, replace some of them, the charitable public will naturally feel inclined to leave the support of all hospitals to the municipality. The poorer classes will be the sufferers, for they will have to pay their share of the increased rates. It may be pointed out that at Bradford, although it has a municipal hospital run on the same lines as the voluntary one, still the latter continues to receive support from the public; but nevertheless I am inclined to think that the existence of such municipal hospitals will inevitably tend to put an end to voluntary support.

I see Mr. Slater agrees with me that in order to bring the transferred Poor Law hospitals up to the standard of the voluntary hospitals it is necessary to appoint visiting specialists on their staffs. But that is not enough to effect the change. There are already visiting specialists on the staffs of some of the large Poor Law hospitals, acting only as consultants. To raise the status of the Poor Law hospitals to that of the voluntary hospitals the whole system of treatment must be altered, so that all patients are admitted under the care of a specialist, and not under the care of a medical officer who is in charge of the whole institution. Dr. MacWilliam says in his letter in the *Journal* of July 20th (p. 125) that in the Walton Poor Law Infirmary at Liverpool specialists have wards allotted to them. This is not so in the large Poor Law hospital in Bristol, and must, I think, be quite exceptional. But even in these wards at Liverpool the specialists do not seem to have complete control over the treatment of their patients, for Dr. MacWilliam says they are "subject to the general responsibility of the medical officer." This seems to me a very undesirable position for any specialist, and one which would not be tolerated in a large city voluntary hospital. In the *Medical Directory* the medical officer is given the first place on the list of the staff, and then follows a list of eight "visiting medical officers," who are not described as in charge of any special departments. This is very far from being comparable to the working of a large city voluntary hospital.

I agree with Dr. MacWilliam when he says that the medical work and nursing in a Poor Law hospital are not as interesting as in a large voluntary city hospital, but when cases are transferred to the city council which would be better dealt with in the large voluntary hospitals, we cannot allot them to a Poor Law hospital simply to interest the staff. Dr. MacWilliam suggests that we should classify patients as "individuals," not by diseases. Does he suggest doing so by their temperaments or the colour of their hair? As for Mr. Slater's representation of my "fantastic" idea of the municipal hospital dump and the voluntary hospital treasure seekers therein, this is really too absurd to need reply.—I am, etc.,

Bristol, July 21st. CHARLES A. MORTON.

SIR,—The problem of the relation of the voluntary hospitals to the municipal hospitals is the same as that which confronts us with regard to trade in the Empire. The voluntary hospitals naturally regard themselves as senior partners, while the municipal hospitals, quite rightly, wish to preserve and foster their growing industries. Given good will, a realization that both exist for the good of the community, and an efficient clearing-house, the problem should not be insoluble.—I am, etc.,

Dulwich, S.E.21, July 22nd. H. M. STEWART.

FEES FOR ATTENDANCE ON DIFFICULT LABOUR.

SIR,—A primigravida was referred to me, by a form for medical help, on account of small pelvic measurements. After several examinations without anaesthetic I was still undecided as to the chances of normal delivery. An anaesthetic for possible induction of labour revealed that Caesarean section was inevitable, my colleague confirming this finding. The operation was performed later with the help of two practitioners. The baby was also circumcized. Apart from this the mother received much treatment before operation for gastric ulcer and burns.

A bill for fourteen guineas, together with a description of the treatment, was tendered to the medical officer to the county. The reply was that there are no provisions for fees outside those covered by the scale of fees, and I am allowed three guineas, including the fee for the anaesthetist.

I am dissatisfied, not only on my own account, but also that the colleagues who so willingly helped me are not to be sufficiently paid. I am anxious to know whether this unfortunate state of affairs exists only in my area: and as I propose to refer the matter to the local Branch of the British Medical Association, I should be grateful for any suggestions, and particularly the experiences of practitioners in this direction.—I am, etc.,

Llanelly, July 24th. RHYS PATON.

Obituary.

THOMAS EAGLESON GORDON, M.Ch., F.R.C.S.I.,

President of the Royal College of Surgeons in Ireland.

WE regret to record the death of Mr. T. E. Gordon, President of the Royal College of Surgeons in Ireland, which took place on July 25th in Dublin. He was a native of the North of Ireland, and had been associated with the Adelaide Hospital in Dublin from his student days until a few months ago, when he resigned on account of trouble with his eyesight and general ill health.

Thomas Eagleson Gordon received his medical education in Dublin, and shortly after he had graduated M.B., B.Ch., in 1880, he was appointed house-surgeon at the Adelaide Hospital, where he had obtained a Hudson Scholarship; he later became assistant surgeon. In 1885 he obtained the diploma F.R.C.S.I., and on the death of Professor Edward Taylor in the same year he went to the Royal City of Dublin Hospital, where he was surgeon for about twelve months. When Dr. Henry FitzGibbon resigned his position as surgeon at the Adelaide Hospital he was succeeded by Dr. Gordon. For many years he was a demonstrator of anatomy in the Medical School of Dublin University, and in 1922 he was appointed professor of surgery; four years later he proceeded M.Ch. He was a member of the Dublin Biological Club, and of the Anatomical Society of Great Britain; he was a Fellow of the Association of Surgeons of Great Britain and Ireland, and of the Royal Academy of Medicine in Ireland, in which also he was president of the Surgical Section. For a number of years he was consulting surgeon to the Rotunda Hospital, Dublin. He was a vice-president of the Section of Surgery at the Annual Meeting of the British Medical Association at Aberdeen in 1914. In addition to conducting a large private practice, he was the London Midland

and Scottish Railway Company's surgeon for Ireland. Outside his professional work he had many interests, two of his chief studies being geology and archaeology. He was the author of a pamphlet, *The Surgery of the Hypertrophied Prostate;* also of an article entitled "Haemorrhagic infraction of the small intestine—successful resection," in the *British Medical Journal*, 1898; of "A case of ununited fracture of head and neck of radius treated by incision" in the *Dublin Journal of Medical Science*, 1897; and of "A successful case of pylorectomy" in the *Transactions of the Royal Academy of Medicine in Ireland*, 1902.

Mr. Gordon's funeral on July 27th was private, but a memorial service held in the Chapel of Trinity College, Dublin, was attended by a large gathering of his personal friends and colleagues. At this service Canon Griffin, a personal friend of the family, paid a high tribute to Mr. Gordon's work in Dublin, making particular reference to his activities in connexion with the Home for Crippled Children, the Adelaide Hospital, and Trinity College Medical School. Professor Gordon, he said, had varied interests apart from his profession; his great desire was to do his work well, and, as they all knew, in the most unobtrusive way. By his death Dublin and Ireland had lost a worthy citizen, whose life was devoted to the well-being of his fellow man. The Royal College of Surgeons in Ireland was represented at the memorial service by the following: Mr. R. Atkinson Stoney, vice-president; Sir Robert H. Woods, Mr. R. C. B. Maunsell, Sir Conway Dwyer, Mr. Trevor N. Smith, Sir C. A. K. Ball, Mr. L. A. Byrne, Mr. Seaton Pringle, Mr. Edward Sheridan, Mr. W. Pearson, Mr. G. E. P. Meldon, Mr. W. C. P. Smyly, Mr. Arthur Chance, and Mr. P. E. Hayden. Owing to absence from Dublin, Sir Thomas Myles, Sir William Taylor, Mr. Andrew Fullerton, and Mr. Howard Stevenson were unable to be present.

WILLIAM DOUGLAS, M.D.,

Past-President, Kent Branch, British Medical Association.

THE news of the death of Dr. William Douglas, at the age of nearly 84, will be received with great regret by a wide circle of friends in the British Medical Association, for he was for many years one of the best known and best liked members of the Representative Body. He was, in fact, the only man who had been a member of that Body and had attended every meeting from its commencement in 1903 up to the meeting at Cardiff last year, and during the whole of that time he represented the Maidstone Division.

William Douglas was the son of Alexander Douglas of Belfast, and was born in that city in 1845. He was educated at Queen's College, Belfast, and in the University of Edinburgh, and took the degree of M.D. of Queen's University of Ireland in 1869. He was for some years in practice at Leamington, and after a time devoted himself entirely to the private treatment of mental disease. He was a member of the Royal Medico-Psychological Association and of the Society for the Study of Inebriety. He travelled very considerably, residing at one time professionally at Madeira, and acting also as a surgeon on the Cunard Line. He took a keen interest in all branches of the profession, and everyone who knew him will remember him as a most interesting conversationalist. But he will chiefly be remembered for the very active part he took in the Irish Medical Schools' and Graduates' Association and in the British Medical Association. Dr. Douglas was recognized as the mainspring of the former society, and was never seen to greater advantage than in the organization and carrying out of its dinners and luncheons. He was for a long time secretary of the society and had been its president; but the mere mention of his official connexion with the body conveys little impression of the keen interest he took in it, and the affection which he inspired amongst his colleagues. He was an active member of the British Medical Association for fifty years, taking a prominent part in the many meetings at the time of the reconstruction of the Association at the beginning of the century, and was a strong supporter of those who believed that the Association would be best served by placing it on a more democratic basis. He took little part in any of the central work of the Association, but was very influential in his own area, and could always be relied upon to do anything within his power for the Association. He was at one time President of the Kent Branch. During recent years he resided at Staines, but advancing age caused no deterioration of his marvellous memory of Association affairs or diminution of his interest in them.

THE MEDICAL SECRETARY adds the following personal tribute:

The loss of my old friend Douglas means for me the breaking of a very close personal and Association tie. He was very proud of his long connexion with the Representative Body, and was a perfect mine of information about its history. Latterly he did not often speak, but he was always listened to with great respect and, indeed, affection. A large number of members of the Representative Body had experienced his hospitality at the functions of the Irish Medical Schools' and Graduates' Association, where he will be very greatly missed. His thoughts up to the last were about that body and about the Representative Meeting. I have been in the habit lately of going to see him whenever I could get an opportunity, and the interest he took in the forthcoming Manchester Meeting, the first he had missed for very many years, was pathetic. I saw him on the Saturday preceding his death, when he asked me to communicate certain wishes about the Irish Graduates' luncheon at Manchester to the present secretary of that body, and sent his best wishes to many of his old colleagues in the Representative Meeting. The above account of his career and these few remarks of mine are a melancholy example of the inefficacy of words to convey to those who do not know the man all that he meant to many of us. I can only add that he was one of the most devoted members of the Association I have ever known, and a most hospitable and kindly gentleman.

THE REV. JAMES M. MACPHAIL, M.A., M.D., C.M.,

Medical Missionary, U.F. Church of Scotland, Santalia, India.

WE regret to record the death in India of Dr. James M. Macphail on June 15th. He had been suffering from dyspnoea for a considerable time, but carried on in his usual cheerful, strenuous way until a week before the end. He was buried at Bamdah the same night, in the place where he had faithfully served for forty years. We are indebted to a medical colleague (D. R.) for the following note.

James Merry Macphail was born in 1863, and was educated at Glasgow. He graduated M.B., C.M. in 1889, proceeding M.D. six years later. Long before he began the study of medicine he had resolved to be a medical missionary, and all his preparation had that end in view. During his medical course he managed to put in attendance at some of the classes in the Theological Hall of the Free Church of Scotland, and he acted for some years as missionary to the Pollokshields Free Church. He spent no time in this country after graduation, but left towards the end of the year for India; he was sent by the Free Church to Bamdah, a village in the Chakai region of Santalia, for work amongst the Santal aboriginals. It was a place where no missionary had been stationed before. It had been visited by preachers from neighbouring stations, and a small congregation awaited him; but there had been no medical work, and he had to start it in a very humble way, gradually winning the confidence of the people and building up a reputation which drew patients from a gradually widening radius. In 1894 a hospital was erected, and the work was carried on with more comfort. Dr. Macphail was particularly interested in eye work, and early made a name for himself in cataract extractions. Many of his patients were pilgrims, and his fame as an operator was carried back by them to villages; after a few years a very large majority of his cataract patients came from villages far distant, even hundreds of miles. From scores of cataract operations yearly, the number soon rose to hundreds, then it passed the thousand mark, and in 1928 reached 2,250. He had a wonderfully dexterous touch, and everything was carried out in the simplest possible manner. On the last occasion on which

the writer had the privilege of visiting Bamdah, now thirty years ago, there was no aseptic surgery; it was all antiseptic, and probably it was the same to the end, as being the most suitable for the surroundings. Macphail's results were amazingly good; failures were few, and generally from causes over which the operator had no control. If a patient chooses to run off from hospital the next day, and removes his bandages in dirty surroundings, he has no cause of complaint if the results are unsatisfactory. In addition to all his medical and missionary work Dr. Macphail was a prolific writer, chiefly in the form of articles to the *Indian Medical Gazette* on professional subjects, and to the *Indian Standard* on scientific, literary, and missionary topics; and all he wrote was well worth reading—sane, interesting, and humorous. He edited two quarterly magazines, *Medical Missions in India* and *Conference*, the latter of which he founded about twenty-five years ago, and continued to edit until his death, as a journal of missionary activities in all parts of India. He published a small manual on eye diseases, called *Eyes Right*, for the use of non-medical readers, a very useful book to place in the hands of missionaries and school teachers in India. He wrote a monograph on *Asoka*, in the Heritage of India Series, which recently reached a third edition, a biography of the late Dr. K. S. Macdonald, and *The Story of the Santal*, of which a translation has recently been published in Copenhagen. He also published for private circulation interesting accounts in diary form of two seasons' touring through his district. A few years after going out to India he married Dr. Jennie R. Wells, a daughter of his late chief, the Rev. Dr. Wells of Pollokshields. She was for some time before marriage in charge of the Mure Memorial Hospital for Women at Nagpur, C.P. Mrs. Macphail has been of immense help to her husband both in his work and in his home. His son Ronald joined him soon after he qualified in 1924.

Macphail was a lovable man, who had many friends, and retained them all. No letter to Macphail remained unanswered long, in fact it became almost a jocular grievance that we were always in his debt, and could never get him into our debt for any length of time. He will be much missed by his many friends, as well as by those among whom he laboured so long and faithfully.

KENNETH ARTHUR LEES, O.B.E., M.B., B.Ch., F.R.C.S.,

Assistant Surgeon, Diseases of the Throat, Nose, and Ear, St. Mary's Hospital.

WE regret to report the death, on July 23rd, of Mr. Kenneth Arthur Lees, after an operation. He was the second son of Dr. D. B. Lees, physician to St. Mary's Hospital from 1887 to 1907, and was born in London in 1881. He received his medical education at the University of Cambridge and St. Mary's Hospital, and obtained the diplomas M.R.C.S., L.R.C.P. in 1907; two years later he graduated M.B., B.Ch., and in 1912 he became F.R.C.S. At St. Mary's Hospital he held in succession the posts of casualty house-surgeon, house-physician, and house-surgeon; he then occupied the post of surgical registrar for two years. For his services during the war he was awarded the O.B.E. In 1919 he was elected assistant surgeon to the department for diseases of the throat, nose, and ear at St. Mary's Hospital, and subsequently obtained the following additional appointments: surgeon for diseases of the throat, nose, and ear, Queen's Hospital for Children, Hackney; and consulting surgeon for diseases of the throat, nose, and ear, Ilford Emergency Hospital; Paddington Hospital; St. Mary Abbott's Hospital; the Victoria Hospital, Swindon; and Letchworth Hospital. Mr. Lees was the author of several contributions to medical literature. He reported a case of ruptured intestine in *St. Mary's Hospital Gazette* in 1916, and in the same journal published an article on chronic suppuration of the middle ear and its adnexa in 1921. His interest in general surgery was indicated by an article based on notes on 900 abdominal sections, which appeared in *The Practitioner* in 1919. He reported two cases of coin in the oesophagus in the *British Medical Journal* in 1927.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

BEFORE Parliament adjourned for the long recess, on July 26th, the Royal Assent was given to the Unemployment Insurance Act, Irish Free State (Confirmation of Agreement) Act, Housing (Revision of Contributions) Act, and other Acts.

The Expiring Laws Continuance Bill was introduced in the House of Commons on July 25th. On the previous day a Widows', Orphans', and Old Age Contributory Pensions Bill was presented by Mr. Greenwood, and a Collecting Charities (Regulation) Bill by Mr. Clynes. The former bill will be debated when the House of Commons reassembles on October 29th.

Radium.

In the House of Commons, on July 24th, Mr. GREENWOOD moved an estimate for £100,000 to defray the charge during the year ending March 31st, 1930, for a grant in aid of the National Radium Trust. He said he had inherited the estimate from the late Government. The purpose of the vote was to augment the supply of radium for the use and treatment of the sick and to advance knowledge of the best methods of radiological treatment. The money would be expended by the National Radium Trust under the terms of a Royal Charter incorporating that body. Earlier this year a subcommittee of the Civil Research Committee had recommended that steps should be taken to ensure the acquisition of an additional 20 grams of radium by instalments for medical purposes. As the result of an appeal from the National Radium Fund, made over the signatures of many medical men, more than £100,000 had been raised by public subscription in a short time. Parliament accordingly was now asked to make this maximum grant of £100,000 to add to the sum obtained as the result of public appeal. Since the recommendations of the Radium Subcommittee had been accepted in principle by the late Government a consultation had taken place with leaders of various branches of the medical profession, and certain minor changes had been made in the proposals of the subcommittee. A Royal Charter had now been received empowering the Government to establish the Radium Trust and the Radium Commission. The Trust would hold the money, and would be responsible for the actual ownership of the radium. The Commission would be responsible for its custody, its care, and its utilization. The Radium Trust would be constituted of the Lord President of the Council (Chairman), the Minister of Health, the Secretary for Scotland, the President of the Royal Society, the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons, England, the Chairman of the Central Liaison Committee for Voluntary Hospitals in Scotland, the President of the Royal Society of Medicine, and the President of the British Medical Association. The Trust was also required to co-opt two medical members of the Commission, and might co-opt not more than three other persons. That was now under consideration. The Radium Commission would consist of a chairman to be appointed by the Trust; four members nominated by, respectively, the Minister of Health, the Secretary for Scotland, the Medical Research Council, and the Department of Scientific and Industrial Research; and six members having special knowledge and experience of the application of radium in the treatment of the sick. These six persons were to be appointed by the Trustees from a panel of twelve, who would be selected by the heads of the medical profession named in the Royal Charter. He understood that there would be a meeting that week which would select the panel of twelve. Within a few days a preliminary meeting of the Radium Trustees would be held. Arrangements were being put in hand as rapidly as practicable in the circumstances, but as these bodies had not yet formally met there might be a little delay in getting the scheme fully into operation. The radium had to be purchased under the most advantageous terms, and the Commission had to consider what were the best ways in which it could be used. The vote was to be accounted for by the Ministry of Health, but the expenditure of the grant in aid would not be accounted for in detail by the Controller and Auditor-General. The Treasury proposed to ask the Auditor-General to audit the accounts of the National Radium Trust and the Radium Commission, and to direct the Trustees to furnish an annual report together with the audited financial statement to Parliament, so that Parliament would keep ultimate control over that part of the fund which had been raised from public sources.

Sir KINGSLEY WOOD said the matter was vital and important, and the expenditure of this large sum represented a considerable step in the campaign against one of the most distressing maladies known to mankind. He was afraid that the cases of cancer in the United Kingdom were on the increase, and up to the moment no investigation had shown what was the real cause of the disease; but radium was certainly one of the most hopeful forms of treatment, and the demands for this were increasing and urgent. The expenditure of the money Parliament was voting was attended with difficulty, because radium was found in very few spots in the

world, and he was almost driven to the conclusion that if the 20 grams of radium was to be obtained immediately the money would have to be expended in practically the only country which was supplying radium in any quantities to-day, and that was Belgium—the supply came from the Belgian Congo. Under the terms of the Charter the purchase of radium was left to the Trustees, but he expressed the hope that the greatest vigilance would be exercised to avoid undue demands being made upon this country in the matter of price. It did not appear as though any of the money could be spent, immediately at any rate, in any part of the British Empire, but he would like to hear whether anything further had been learnt regarding the possibilities of Australia, which, according to the report of the Radium Subcommittee, were engaging the attention of the Commonwealth Council of Scientific and Industrial Research. It would be a great blessing to mankind, and desirable also from the point of view of expenditure, if radium were found in Australia or in any other part of the British Empire. He did not say, and had no evidence, that there was anything in the nature of a hold-up of radium in the one source to which the Trustees could go. The process of extracting radium was a very expensive one, and considerable capital had to be sunk. A suggestion had been made that the purchase of radium should be entrusted to the League of Nations, and that idea might be achieved some day, but in the interval the urgency of obtaining radium for the United Kingdom was very great. It was a matter for regret that while the radium practice in this country was as good as in any other, such countries as Sweden and France were ahead of us in the provision they made for the treatment of people suffering from cancer. He suggested to the Minister of Health the advisability of increasing the number of surgeons associated with radium treatment. They not only required a good deal more radium, but they wanted many more skilled persons to administer it. Radium, if used unskilfully, could cause tremendous mischief. He further asked the Minister to ensure that when the distribution of radium was made there would be fair treatment of the various hospitals up and down the country. Up to the present time there had been great waste, having regard to the amount of radium available, and he thought that various types of disease likely to be successfully treated by radium should be concentrated in certain centres. Recognizing the individual interests of hospital associations he was afraid that suggestion might be difficult in practice. France had a dozen special centres for the treatment of various diseases by radium, and so was able to save a good deal of waste and to use radium more to the advantage of the people than we could do while our centres were scattered up and down the country among a large number of institutions. He was sure the estimates would meet with approval in all parts of the House.

Mr. SOMERVILLE HASTINGS hoped the committee would agree with the supplementary estimate. The terrible need for radium was constantly being pressed upon him. Like many other members of his profession who dealt with cancer, he constantly found that he needed radium for the treatment of patients, and it was very hard to obtain. On the previous morning in hospital he saw many cases of cancer, and for two of them radium was required. He asked the radium officer of the hospital how soon a supply of radium could be obtained, and he said not for a month in either of those cases. While those patients were waiting, and he was waiting to carry out the proper treatment, the disease must steadily advance. The same thing occurred in other hospitals. On the day after that debate he hoped to treat cancer with radium, but he had waited twenty days to obtain the necessary supply commercially. He regretted to agree with Sir Kingsley Wood that during the last few years Sweden and France had made much greater advances in radium treatment than had this country. The Government of France possessed 31.5 grams of radium, which it allocated to various treatment centres, whereas the Government of this country, through the Medical Research Council, possessed no more than 2.4 grams. Two years ago Mr. Hastings had occasion to investigate the results of radium treatment of cancer of one organ of the body, which involved the result of an experience of some fifteen years. When he looked carefully into these results he had to confess they were unsatisfactory. Good had undoubtedly been done in some cases by treatment, but he could not point with confidence to a certain patient that had been cured. To-day things were different. During the past two years extraordinary advances had been made, and surgeons now were able to do with radium what they never dreamt was possible two or three years ago. In the opinion of many surgeons it was now better to treat many forms of cancer in their early stages by radium rather than by cutting away the growth, because the radium treatment left the condition of the patient much more like the normal. No fewer than 54,000 people died of cancer in the United Kingdom in 1927, and many of those lives might have been saved had there been sufficient radium in this country to give them the necessary treatment. Treatment by radium was not simple. It required experience and research. In his opinion the advances made in this country were very largely due to the wise use which the Medical Research Council had made of the 2.4 grams which the Government placed in their charge. Efficient treatment by radium meant that there must be careful, painstaking research and pooled experience. When these two things were combined they would get the advance which they all desired. He wished the Government had undertaken a bolder policy than giving pound for pound for the money collected by voluntary subscription. The shortage of radium in this country seemed to him a national disgrace, and to give a fair prospect of cure to those suffering from cancer appeared to him a national duty which the Government should shoulder completely. He hoped that next time the Government dealt with the sick of this country it would go the whole way.

Sir CHARLES CAYZER asked for an assurance that the provincial hospitals would get equal treatment with the London hospitals in the distribution of radium. What would be the position of provincial hospitals when they came to buy radium themselves with money which they had themselves raised locally? Would they have the right to send the funds they had raised to the central Commission, and to ask that Commission to buy for them? He further asked for an assurance that the provincial hospitals would have a representative on the Radium Commission.

Mr. HAYCOCK expressed his disapproval of the smallness of the vote. Something like one in seven of the population died of cancer, and £100,000 would only pay for treating sixty-six women. The cost of radium salt used surgically on the breast was £1,500, compared with £800 for the brain and £120 for the tongue. He believed that not one person in fifty who ought to get the treatment was getting it, and he pointed out that the £100,000 voted was not merely for radium salt, but to provide for research. It did not pay individual surgeons to invest their time and money in learning how to use radium. There was a surgeon in Manchester who, if he had devoted his time and his great abilities to an ordinary practice, would have made a large income. That man, after investing his best abilities and his capital, was rewarded by poverty, and the hat had to go round to provide him with the ordinary necessities of life. It was a disgrace and a shame that the men who were doing something to make this world less a home of agony could not provide for their old age or ill health. Sir Ronald Ross, perhaps the greatest benefactor of the human race now alive, was dependent on the mercies of charity. As regards the supply of radium, he reminded the committee that in 1904, long before the deposits of uranium were discovered in the Congo, radium cost from £2 to £4 per milligram. In spite of the fact that the process was enormously simplified, the price in 1923 was over £11 per milligram. He suggested that the Government might think of controlling a home supply, of investing money in securing a source of raw material by buying areas where pitchblende existed, and thus getting radium at a less price than in 1904 instead of at the present price.

Commander BELLAIRS said the monopoly of radium was a monopoly of something which was required by medical science and research in every nation. If a nation extorted monopoly prices every endeavour ought to be made through the League of Nations to bring that nation to reason. If necessary, that nation must be pilloried before the whole world. The sum asked from Parliament was a small one, but was a beginning. He thought that before long the State would be contributing something like £1,000,000.

Mr. ROBERT MORRISON said the prices charged by Radium Belge, which held the monopoly, were £10,000 per gram to European countries, £12,000 per gram to Great Britain and some colonies, and £14,000 to America. The principle was that the more money a country had the more it had to pay. Were the Radium Trustees to buy radium from Radium Belge at its own price and make no effort to obtain more? He hoped someone might be co-opted to the Board who could deal with the vital question of where supplies of radium could be obtained. The Trustees should receive further powers to discover new sources of supply.

Miss SUSAN LAWRENCE said Mr. Hastings had spoken with full knowledge of the need for additional supplies. When the Government took office the scheme was in an advanced state, the constitution of the two committees had been decided, and neither the medical profession nor the sufferers would have thanked Ministers if they had held up the vote for six months to get a better scheme. The main business of the Trust would be the purchase of radium at the best prices, and it would explore all possible sources. By the fact that there would be one big buyer instead of a number of little buyers it was far more likely to obtain the substance at reasonable prices. The Committee of Civil Research had mentioned Australia as a source of radium, and was anxiously exploring every possibility. The Commonwealth Government was considering the possibilities of radium in Australia. The House must exercise patience, and would be better able to judge prices when the Trust had been functioning some time. The object of the Radium Commission would be to secure not only a fair distribution of radium between hospital and hospital, but a division which would secure the most profitable and continuous use of radium. The substance was capable of continuous use, and could be used far more profitably if treatment could be concentrated in centres able to take such a number of patients as would ensure continuous use of the remedy. It was calculated that the money available—£384,000—would buy about 17 grams of radium, and the experts held that that was as much as could be used at present. The difficulty was not so much the purchase of radium as to secure

a sufficient number of medical men and assistants capable of handling this substance. That was engaging the attention of the Minister of Health, who hoped to make some announcement on the training of medical men and assistants. Mr. Haycock was wrong about the cost of treatment by radium. The quantity required to treat one case might cost £1,500, but the same little pinhead of substance would treat case after case. In a short time this beneficent work would begin. A report on it might very properly be issued by the Minister of Health. The Lord President of the Council, as chairman of the Commission, would be responsible for answering questions in Parliament on its behalf, and the House of Commons would have no difficulty in securing information. She added that the supply of radium was already engaging the attention of the League of Nations.

The House then agreed with the resolution to vote £100,000. This resolution again came before the Commons on the report stage the next day, July 25th.

Commander KENWORTHY remarked that international action would be needed to conserve and distribute the supplies of radium and to prevent undue increases in its price. At present one Government competed against another. The Australian Government had taken steps to buy £130,000 worth of radium. The Swedish Government had bought a number of grams, and the Greek Government had done the same. He asked the Minister of Health to pursue inquiries into this aspect of the question.

Captain BOURNE asked whether the Radium Commission was to be a profit-making body, letting out the radium, or whether it would make free grants to hospitals.

Mr. GREENWOOD, in reply, said he imagined the Trust would co-operate with any other nation to get its supply at the lowest possible price. That problem was causing anxiety in other countries. The Health Section of the League of Nations already had radium under its notice, and had issued a technical report. The method of buying radium was for the Radium Trust to decide, but the general idea was purchase by instalments. If it went into the market to buy £250,000 worth it might easily put up the market against itself. It was not proposed that the Commission should operate at a profit. Local hospitals would not be given radium; they would be lent it, and it would continue to be held legally by the Radium Trust. A small charge for the loan of the radium would be made against the cost of administering the scheme.

The House then agreed with the resolution as reported.

Colonial Development Bill.

At the close of a debate, on July 12th, upon a Government motion to authorize Treasury advances by grant or loan for colonial development, Dr. VERNON DAVIES said he was glad that Mr. J. H. Thomas, who was in charge of the motion, recognized the importance of health services. He asked him to think not only of colonial health services against tropical diseases, but to bear in mind also the question of venereal disease. The medical services often had to be the advance guard in imperial or colonial development. Mr. Thomas should see that the colonial medical services were in a position to meet any sudden demand. If the projected development were achieved suddenly the medical service might be found not to have the full personnel that was needed. In cases where schemes of development were handed over to private firms the medical services should be maintained under the colonial medical administration. Instead of ordinary medical men going out without much experience let them keep the colonial medical service in the hands of the colonial medical authorities.

On July 17th Mr. LUNN moved the second reading of the Colonial Development Bill, based on the motion of July 12th. He said that in the previous debate on the financial resolution emphasis had been put on the medical services, and speakers had urged that these should be considered in schemes of colonial development. Many schemes had been undertaken in recent years by this and other countries in which that aspect had been closely considered. Experience proved the wisdom of giving attention to the health conditions of those who laboured in these great enterprises. He assured the House that in any new schemes of colonial development the medical services and medical research work for the improvement of health conditions would find a very important place.

Lord EUSTACE PERCY asked the Government to make sure that grants for health services would not be excluded from the bill.

Sir HERBERT SAMUEL suggested that the Advisory Committee proposed under the bill should have at least one person who would make it his duty to promote all kinds of research.

Lord WINTERTON said Parliament had responsibility to indigenous Africans, who were entitled to protection against diseases in themselves and their cattle.

Sir HILTON YOUNG condemned the manner in which an undivided fund was provided for research and for industrial development under a single committee. These subjects should be separated at the outset.

Sir OSWALD MOSLEY, for the Government, said, in answer to Lord Eustace Percy, that the bill would admit expenditure on diseases which affected persons engaged in industry and impaired their efficiency. Such diseases as hookworm could certainly be dealt with under the bill.

Dr. VERNON DAVIES asked why health was not included specifically in the bill.

Sir OSWALD MOSLEY said Dr. Davies's fears were not justified.

The bill was read a second time.

On July 18th the House of Commons went into committee on the bill. Sir OSWALD MOSLEY moved to add to the authorized purposes of expenditure "The promotion of public health."

The House accepted the amendment. Subsequently Sir OSWALD MOSLEY admitted that to divide research from development would be better, but it should be done when the machinery of the Empire Marketing Board was dovetailed with that of the present bill.

The bill then passed through committee, and after the third reading, on July 19th, was sent to the House of Lords, where it was read the first time on July 22nd and the second time on July 23rd.

Post-vaccinal Encephalitis.

In an answer to Mr. Broad, on July 22th, Mr. GREENWOOD said rabbits had been systematically used in the production of Government lymph since 1902, whereas no case of post-vaccinal encephalitis was reported in England and Wales till December, 1922. Discussion with the use of rabbits had been considered, but no change in the present practice was deemed necessary.

Mr. FREEMAN asked whether, in view of the deaths which had followed vaccination, the Ministry would institute a full inquiry into the subject, with the object of avoiding such deaths and unnecessary cruelty to animals.

Mr. GREENWOOD replied that there was no indication that these deaths necessarily arose from the use of rabbit lymph. The question of deaths from encephalitis was under continuous and very serious consideration.

Mr. CHAMBERLAIN asked whether a committee had investigated this question under the chairmanship of Sir Humphry Rolleston.

Mr. GREENWOOD said that was so. The committee had made recommendations for further research, which was now being carried on.

Mr. BROAD asked whether the Minister of Health was prepared to guarantee that any child or person vaccinated with Government lymph would not be seriously injured by the operation; and, if that were not possible, whether he would consider the desirability of introducing legislation to secure that compensation should be given in such cases to parents or dependants.

Mr. GREENWOOD said it was impossible to give an absolute guarantee that no person vaccinated with Government or any other lymph would suffer injury, but lymph produced by the Government lymph establishment complied in all respects with the standards laid down in the regulations made under the Therapeutic Substances Act. As at present advised he could not introduce legislation to provide for payment of compensation.

Answering a further question by Mr. Broad, Mr. GREENWOOD said no funds were at his disposal out of which grants could be made to parents for funeral expenses in cases where a fatal result ensued after vaccination by public vaccinators.

Mr. GREENWOOD told Mr. Freeman, on July 25th, that his attention had been called to the case of a boy, aged 12, of East Ferry Road, Cubitt Town, who died on July 20th, after being vaccinated on July 3rd. He was informed that Government lymph was not used.

Deaths from Bovine Tuberculosis.—On July 23rd Dr. FREMANTLE asked if the Minister of Health was aware that over 2,000 infants died every year from bovine tuberculosis. Miss LAWRENCE said the Minister of Health was advised that it was not possible to ascertain precisely how many infants died each year from bovine tuberculosis, but such evidence as was available suggested that the number was less than that given in the question. Bovine tuberculosis was mainly conveyed by milk, but she had no information to support the figure of £9,000,000 a year which Dr. Fremantle calculated to be the expenditure on treatment, convalescence, and after-care of this disease in infants. Dr. FREMANTLE suggested that measures should be introduced to secure that only milk free from tubercle should be given to infants attending the 3,000 existing infant welfare centres. Miss LAWRENCE replied that dried milk was supplied at most of these centres. This was recommended by the Ministry of Health in any case in which the ordinary milk supply was of doubtful quality. A few local authorities supplied tuberculin-tested milk, but it would not be practicable to require such a supply in every case, nor would such a requirement be justified having regard to the many available supplies of dried milk of reliable brands.

[Owing to the great pressure on our space this week we are compelled to hold over a few notes until our next issue.]

The Services.

THE Royal Naval Volunteer Reserve Officers' Decoration has been awarded to Surgeon Lieutenant Commander J. Lorimer, R.N.V.R.

NAVAL MEDICAL COMPASSIONATE FUND.

AT the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on July 3rd, under the chairmanship of Surgeon Vice-Admiral Arthur Gaskell, C.B., Medical Director-General of the Navy, the sum of £40 was awarded to the only applicant.

Universities and Colleges.

UNIVERSITY OF LONDON.

MISS EDITH GUEST, M.A., M.D., has been appointed honorary assistant in the Department of Egyptology. In the Department of Anatomy and Embryology Miss Doris Dingwall and Miss Mary Levine have been appointed honorary assistants, and Mr. R. W. Haines honorary demonstrator. In the Department of the History of Medicine Mr. J. S. Prendergast has been appointed honorary research assistant.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

Division of Tropical Medicine and Hygiene.

The following have successfully passed the school examination at the termination of the eighty-sixth term (March–July):

*S. Taneja (Duncan medal), *M. A. A. El Gammal, *A. H. Lowther, *S. J. De Navasquez, *R. W. Scanlon, *H. A. Yenikomshian, [illegible] C. [illegible], *I. Arndt, Sh. Atta-Ullah, [illegible] rnard, H. Birmingham, D. B. Clay, W. G. Evans, Fraser-Smith, K. K. Goh, Husinim, R. C. Jones, [illegible] O. W. A. Mahon-Daly, McCarthy, S. K. Mitra, L. H. Mottet, C. P. Murray, H. M. O'Connor, R. F. Pinson, T. Simpson, J. T. Smith, C. E. Soodeen, R. Stuart, D. R. Thapar, M. A. Ullah, G. N. Unnithan, K. C. Yost.

* Passed with distinction.

UNIVERSITY OF MANCHESTER.

THE following appointments are announced: Lecturer in clinical medicine, Dr. E. Beaslin Leech; demonstrators in anatomy, Mr. F. H. Bentley and Dr. R. P. Osborne.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

AT a meeting of the Royal College of Surgeons of Edinburgh held July 23rd, when Mr. Alexander Miles (President) was in the chair, the following 27 successful candidates (out of 81 entered) who passed the requisite examinations between March 21st and 28th were admitted Fellows:

G. Brown, Eva T. Cairns, J. Campbell, K. R. Chaudhri, D. B. Craig, R. A. Grant, G. Y. Graves, T. P. Gill, D. Hardie, A. T. Henry, R. S. Jones, G. D. Kapur, J. K. R. Landells, D. P. McDonald, G. H. Mahony, M. Y. May, A. Patrick, W. V. Semple, W. S. Shearer, B. Singh, N. Singh, W. C. Spackman, R. S. Stevenson, G. M. Sturrock, A. B. Taylor, M. K. Tucker, G. S. Thompson.

The Ivison Macadam Memorial Prize, consisting of a bronze medal and a set of books, was, after a competitive examination in organic chemistry, awarded to Mr. C. D. Campbell.

Dr. H. P. Lal, having passed the requisite examination on July 12th, obtained the diploma of L.R.C.S.Edin.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the Royal College of Physicians of London was held on July 25th, when the President, Sir John Rose Bradford, was in the chair.

Election of Officers.

The following officers were elected for the ensuing year:—*Censors:* Robert Hutchison, M.D., James S. Collier, M.D., R. A. Young, C.B.E., M.D., W. C. Bosanquet, M.D. *Treasurer:* Sidney P. Phillips, M.D. *Registrar:* Raymond Crawfurd, M.D. *Harveian Librarian:* Arnold Chaplin, M.D. *Assistant Registrar:* R. O. Moon, M.D.

Appointment of Representatives.

Dr. H. Letheby Tidy was elected representative of the College on the General Medical Council, in succession to Sir Farquhar Buzzard, and Sir Ewen Maclean a representative on the Advisory Medical Board of the University of Wales. Sir Maurice Craig was appointed a delegate to the Conference of the National Council of Mental Hygiene, to be held in October, and Dr. Maurice Davidson a delegate to the fifteenth annual Conference of the National Association for the Prevention of Tuberculosis at Newcastle-upon-Tyne in October.

Medals and Scholarships.

The Baly Medal for distinction in the science of physiology was awarded to Dr. Edgar Douglas Adrian, F.R.S., and the Bisset-Hawkins Medal for advancing sanitary science and public health to Professor Edward Mellanby, F.R.S. The Murchison Scholarship was awarded to Ian G. W. Hill, M.B., of Edinburgh University. Professor J. B. Leathes was appointed to deliver the Harveian Oration and Dr. W. E. Hume the Bradshaw Lecture in 1930.

Lectures.

The following further appointments were announced: Dr. Andrew Balfour as FitzPatrick Lecturer for 1930, Dr. Carey F. Coombs as Lumleian Lecturer for 1930, Dr. Donald Hunter as Goulstonian Lecturer for 1930, Dr. J. J. R. Macleod as Oliver-Sharpey Lecturer for 1930, Dr. L. S. T. Burrell as Mitchell Lecturer for 1930, and Dr. M. J. Stewart as Croonian Lecturer for 1931.

Vote of Thanks.

The thanks of the College were voted to Sir Wilmot Herringham and Dr. John Fawcett for their valuable and lengthy services as representatives of the College on the Senate of the University of London.

The "Nomenclature of Diseases."

The President nominated a committee for the preparation of a new edition of the official *Nomenclature of Diseases.*

Membership.

The following gentlemen, having satisfied the Censors' Board, were admitted Members of the College:

William Wray Barraclough, M.B.Toronto, Richard Alan Brews, [illegible], M.B.Liverp., Geoffrey Pretor [illegible] nan, M.B.Manch., Frederick [illegible] B.Lond., Kenneth Alexander Campbell Golding, M.B.Syd., [illegible] Hartsilver, L.R.C.P., Aubrey [illegible] Julian Lewis, M.B. Adelaide, [illegible] M.B.Camb., Charles [illegible] s Twining McNath, [illegible] ncis John Niall, [illegible] ghunath Saran, [illegible] Gordon Murray

Licences.

Licences to practise physic were conferred on the following:

C. Abraham, S. Annaswami, M. A. E. Anous, S. W. K. Arundell, *†Nancy M. Badeley, C. P. Bailey, E. F. Barnardo, D. W. Bawtree, D. R. Belletty, M. J. Bennett-Jones, H. J. W. Bergh, W. R. Bett, P. M. F. Bishop, R. M. Bolan, *Bertha A. Briant, C. E. Brie, V. I. C. Cadogan, E. H. Cape, P. A. Cooper, W. J. Cotton, P. Dalzell, A. C. Dawes, *†Catherine Day, *Jessie E. Dodds, C. E. Dolman, W. J. L. Downing, G. Duckworth, T. F. H. Duffell, D. H. A. Edmondson, L. M. Edwards, J. L. Egan, *Cordelia H. England, I. Q. Evans, M. D. A. Evans, R. G. P. Evans, D. Ezekiel, R. B. H. Faichney, M. Farid, W. J. Ferguson, J. A. Fernandez, K. S. Fitch, S. K. Foster, W. W. Fox, A. W. Franklin, A. Freitag, R. L. Frost, *Ruth C. Galletly, S. Gasson, N. D. Gerrish, J. J. J. Giraldi, *Elizabeth L. Haden, Hafizuddin, *Nellie M. E. Hallinan, *†Margaret L. Hamburger, A. G. J. Harris, R. L. H. Harris, F. Hawking, *Dora M. Hill, R. E. Holmes, I. P. G. Howells, W. V. Howells, J. M. Hulett, *Laura F. Hutton, D. E. Hyman, K. G. W. James, S. K. Jatar, A. N. Jones, D. S. Jones, H. H. Kenshole, T. H. Khan, C. W. Kidson, S. Knight, M. Kokia, M. Kremer, J. Libman, F. J. G. Lishman, M. Luckeenarain, S. D. McClean, [illegible] S. W. R. Nottis, [illegible] each, W. Pearce, [illegible] Prowse, W. Rad- [illegible] W. H. Reynolds, P. J. Richards, K. M. Robertson, J. A. Robson, *Irene H. Rogers, [illegible] K. Sconce, J. M. Scott, [illegible] Simon, A. R. Smith, [illegible] tor, E. W. Thompson, [illegible] H. Wace, J. V. Walker, R. Warnecke, J. A. White, J. O. Williams, J. K. Wilson-Pepper, *Camille Wiseham, M. G. Woolff, L. C. Wright, P. Yarmarko, D. J. Young.

* Under the Medical Act, 1876.
† M.R.C.S. previously granted.

Diplomas.

The following diplomas were conferred, jointly with the Royal College of Surgeons:

PUBLIC HEALTH.—K. P. Anklesaria, D. D. Bhargava, D. L. Brown, H. A. Bulman, Helen Bumstead, K. Cathiravelu, K. B. Chakravarti, A. N. Chatterjee, M. Das, A. W. H. Donaldson, D. C. Farquharson, L. S. Farquharson, J. W. Fisher, L. Fourie, Hilda M. Garlick, D. Hughes, A. T. [illegible], A. Macmillan, [illegible], Joan Nixon, J. [illegible], J. H. Stritch, R. [illegible]

OPHTHALMIC MEDICINE AND SURGERY.—[illegible], P. K. Banerjee, W. A. Briggs, R. D. [illegible], Costobadie, T. Edmunds, Julia M [illegible], Gibbons, S. L. Geerin, J. R. McC [illegible], M. D. Nunan, P. Pattabhiramaiya, A. N. Ponnambalam, C. S. V. Ramanan, K. Sen, L. B. Somerville-Large, B. R. Tandan, M. Tree, T. K. Uttam Singh, D. G. Vyas, G. B. White.

PSYCHOLOGICAL MEDICINE.—L. Barber, Flora H. MacD. Calder, Viola C. Cameron, Ruby T. Carr, S. W. Davies, J. H. Ewen, E. A. Haslam-Fox, J. E. S. Lloyd, S. V. S. Rao, Kathleen M. Todd.

LARYNGOLOGY AND OTOLOGY.—B. R. Chaudhri, P. Hickey, G. J. Hutchison, R. Kacker, W. A. Kerr, K. S. May, R. F. Paterson, C. L. Rosenfield, G. Vaishnavi.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—C. E. P. Davies, W. M. Hamer, A. Hamid, C. Horton, V. J. Lopez, W. McDermott, K. M. Seedat, V. J. C. Vandenbosch, T. K. White.

MEDICINE.—A. Campbell, V. N. Datta, A. N. de Monte, C. Parthasarthe, C. F. H. Quick, P. U. Rao, A. Somerville.

FORENSIC MEDICINE.—V. N. Datta, E. T. Garthwaite, J. Gordon, C. Parthasarthe, C. J. Poh, C. F. H. Quick, P. U. Rao.

MIDWIFERY.—A. R. Edwards, R. W. Goldsbrough, P. D. Kapur, E. Marks, C. J. Poh, S. V. S. Rao, T. G. Robinson, G. W. Sturgess.

The diploma of the Society has been granted to the following candidates: A. Campbell, V. N. Datta, C. J. Poh, C. F. H. Quick, P. U. Rao, K. M. Seedat.

Medico-Legal.

WORKMEN'S COMPENSATION: EFFECT OF MEDICAL REFEREE'S CERTIFICATE.

THE legal effect of a certificate of complete recovery given by a medical referee in accordance with the terms of Subsection 3, Section 19, of the Workmen's Compensation Act, 1925, was argued before the House of Lords in the case Wilsons and Clyde Coal Company, Ltd., v. Burrows, and, in the judgements delivered on July 18th, it was unanimously held that where a certificate given by the medical referee was unambiguous the arbitrator must accept it as final.

The case was one in which the workman received compensation for injuries to his back by an accident arising out of and in the course of his employment, and on three occasions the question of his condition and fitness was referred to a medical referee. The third certificate, given on October 18th, 1928, said the workman had completely recovered, but in the proceedings before the Sheriff-Substitute of Lanarkshire, as arbitrator, the workman lodged a minute stating that skiagrams taken since the giving of the certificate disclosed conditions not apparent on external examination, and that there was a reasonable probability of incapacity. The arbitrator refused to remit the matter to the medical referee for further report, however, holding that the certificate was unambiguous and ending the compensation. The Second Division of the Scottish Court of Session was appealed to on two questions of law: whether the arbitrator was right in refusing to re-remit the case to the medical referee for further certificate, and whether he was entitled to end the compensation. It was held that the arbitrator had a discretion to re-remit which he had duly exercised but, without answering the second question, the Second Division remitted the case to the arbitrator to inquire into the facts set out in the workman's minute lodged after the medical referee's certificate was given.

The employers appealed to the House of Lords against the remission, and Lord Dunedin, in his judgement—in which the other members concurred—drew an important legal distinction between the duties of the arbitrator and of the medical referee. He characterized the remission as a departure from procedure of a grave character as tending to interfere with the carrying out of the Workmen's Compensation Act. The arbitrator's duty was to inquire whether there was an accident, whether the injury resulted therefrom, and whether it arose out of and in the course of the employment. The medical referee's duty was to determine the question of recovery. This, the Legislature had made clear, was a better method than by more proof before an arbitrator. Lord Dunedin detailed the procedure relating to medical examinations in Sections 17 and 18, and relating to a further examination by a medical referee in Section 19 where the parties failed to agree, and emphasized the fact that it was the duty of the workman to bring to the notice of the medical referee such a matter as a reasonable probability that the injury might break out again in the future. Of course, if the certificate of the medical referee had been ambiguous it was competent for the arbitrator to remit it back to the medical referee, but as here in this case the certificate was not ambiguous it was clearly for the arbitrator to accept it as final.

The arbitrator was right in treating the medical referee's certificate as final and in stopping compensation, and therefore the appeal was allowed.

CHLORODYNE: FALSE TRADE DESCRIPTION.

Over a qualified chemist is entitled under the Pharmacy Act to sell poisons [illegible] on the other hand, any unqualified chemist who professes to the public that a particular drug compound [illegible] a poison when it, in fact, it does not, is liable to prosecution under the Merchandise Marks Act either for applying a false trade description to the goods or for selling such goods or even for having such goods in his possession. The case of Chandler v. Boots is an example of the risk of contravening the Act [illegible] by drug-store keepers who do not keep [illegible] on their premises. In selling a bottle described as containing "chlorodyne" which in fact, does not contain [illegible] a drug-store keeper commits no offence, either under the Pharmacy Act [illegible] under the Merchandise Marks Act [illegible] to the description he adds "B.P.85" he commits the [illegible] complies with the [illegible] according to the formula given in the British Pharmacopœia of 1925 and there [illegible] under the Merchandise Marks Act. [illegible] Hawkins, Limited, [illegible] at Manor Park, Ilford, [illegible] manufacture at East Ham [illegible] £20 and £5 5s. respectively [illegible] fraud if a preparation sold with the label 'B.P.85' is without morphine." The fact that no offence is committed by a chemist, whether qualified or not, who applies the word "chlorodyne" to a bottle of fluid which, in fact, contains no morphine, is probably explained by the prosecuting solicitor's remark that chlorodyne was originally a proprietary medicine, but that the term had now come to be applied generically to other similar preparations, but not necessarily of the same formula. The inference to be drawn from this statement is that there are preparations of this kind not containing morphine, to which a chemist may apply the word "chlorodyne" without committing an offence under the Merchandise Marks Act.

Medical News.

SIR DONALD MACALISTER, Bt., M.D., who has been Principal and Vice-Chancellor of the University of Glasgow since 1907, has announced his intention to retire from the Principalship in October next.

MR. SAMPSON HANDLEY has now returned from his visit to Australia and New Zealand in the capacity of official delegate of the British Medical Association to the Annual Meeting of the New Zealand Branch.

Dr. William J. Mayo and Dr. Charles H. Mayo of Rochester, U.S.A., visited the Eccles and Patricroft Hospital, Manchester, on Thursday, July 25th, and inspected the surgical wards. They were offered and accepted the positions as patrons of the hospital. Professor A. H. Burgess, President of the British Medical Association, and Professor W. Harvey Smith (Winnipeg), President-Elect, also visited the hospital.

THE Fellowship of Medicine announces that a special course in urology is being held at All Saints' Hospital, Vauxhall Bridge Road, and will continue throughout the present month. From August 12th to 21st a whole-day course in diseases of children at the Queen's Hospital for Children, Bethnal Green, will include operations, demonstrations, and lectures. The following arrangements have been made for September: a whole-day course in diseases of the chest at the Brompton Hospital from September 9th to 14th; an afternoon course in diseases of infants at the Infants Hospital from September 9th to 21st; a course in psychological medicine at the Bethlem Royal Hospital on Tuesday and Saturday mornings at 11 a.m., from September 10th to October 5th; a whole-day course in medicine, surgery, and the specialties at the Westminster Hospital from September 16th to 28th, for men only; and a whole-day course in gastro-enterology from September 30th to October 4th at the Prince of Wales's Hospital, Tottenham. Intending entrants are asked to communicate as soon as possible with the Fellowship of Medicine. In October two courses in addition to the list for 1929 already published will be held. One, an evening course in preparation for the M.R.C.P. examination, will consist of lectures on Tuesday and Friday evenings at 8.30 p.m. at the Medical Society's lecture room, 11, Chandos Street. The second additional course in medicine, surgery, and the specialties will be held at the Metropolitan Hospital, Kingsland Road, from October 21st to November 2nd. Full particulars of all courses can be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE National Council for Mental Hygiene, in association with the Joint Committee of the National Council for Mental Hygiene and the Tavistock Square Clinic, has arranged a conference on mental health, to be held in the Central Hall, Westminster, from October 30th to November 2nd. The main subjects for discussion are: sex education; the personal equation in industry; the child and the parent; and delinquency—a problem in mental hygiene. Further particulars may be had from the conference secretaries, 51, Tavistock Square, W.C.1.

THE Department of Scientific and Industrial Research has published an index to the literature of food investigation. The first number, dated March, 1929, covers publications up to last January. It is proposed to issue these lists twice a year, and it is hoped that in this way workers in different parts of the Empire will be put in touch with each other. A brief historical review of the subject is included in this first number, and the general bibliography is arranged under such headings as: meat; fish; eggs; dairy produce; fruit and vegetables; theories of canning, freezing, and chilling; bacteriology; and engineering. The price of this issue is 2s. net, and it may be obtained in England from H.M. Stationery Office, or in America from the British Library of Information, French Buildings, 5, East 45th Street, New York.

THE Health and Cleanliness Council, which was inaugurated in 1925, reports its activities in the form of occasional bulletins, of which the seventh, just published, contains an account of the third annual general meeting of the council,

and of its propaganda work as conducted by means of the travelling cinema, lectures and demonstrations at health weeks, and poster and publication campaigns. Among the posters is a new one warning against the dangers caused by flies; it may be had free on application. Particulars of the council's work may be obtained from its secretary, 5, Tavistock Square, W.C.1.

WE are informed that *A System of Bacteriology in Relation to Medicine*, by various authors, is being prepared under the auspices of the Medical Research Council and published by H.M. Stationery Office. It will be issued in nine volumes, each of some 400 pages, the earliest of which (Volume III) will appear in the latter part of August, and the others at intervals of a few months. Nearly a hundred British bacteriologists are collaborating in this work, the aim of which is to give a comprehensive but not encyclopaedic survey of our present knowledge of bacteria and spirochaetes, with special regard to their relations to the various fields of medical work.

THE International Medical Group for the Investigation of Birth Control, formed in 1927 to facilitate the exchange of information on the subject of birth control between members of the medical profession in different countries, has issued in pamphlet form a compilation, edited by Dr. C. P. Blacker, of the reports received from the medical representatives of the group in America, Austria, Germany, Great Britain, Spain, and Sweden. The pamphlet contains useful information on the legal status of contraception and the attitude towards the subject of the medical profession and the general public in the various countries under survey, an account of the researches now in progress under the auspices of the Birth Control Investigation Committee, and a paper by Dr. B. P. Wiesner, of the Animal Breeding Research Department, Edinburgh, on controlled fertility by means of hormonic interference. Copies, price 6d., may be obtained from the Hon. Mrs. M. Farrer, 41B, Clanricarde Gardens, W.2.

THE late Dr. George Thompson Henderson has bequeathed £5,000 to Guy's Hospital, the income to be used for the general purposes of the hospital other than the medical school or college.

NO. 8 of Vol. 2 of the Summary of Current Literature, issued periodically by the Water Pollution Research Board's Department of Scientific and Industrial Research, has now been received, and may be consulted in the Library of the British Medical Association.

THE Thirty-eighth French Congress of Surgery will be held in Paris under the presidency of Dr. Tixier, professor of clinical surgery at Lyons, from October 7th to 11th, when the following subjects will be discussed: Indications for, and results of, osteo-synthesis in Pott's disease, introduced by Roche of Bordeaux and Sorrel of Paris; evolution and treatment of wounds of the tendons of the hands, introduced by J. C. Bloch of Paris and P. Bonnet of Lyons; surgical treatment of pulmonary tuberculosis, introduced by L. Bérard of Lyons and G. Lardennois of Paris. Further information can be obtained from the general secretary, 12, Rue de Seine, Paris.

DR. J. HUGH THURSFIELD has been elected a governor of St. Bartholomew's Hospital.

DR. ARTHUR E. GILES, consulting surgeon, Chelsea Hospital for Women, has been elected Master of the Drapers' Company.

THE following appointments have recently been made in foreign faculties of medicine: Professor Paul Heim of the University of Fünfkirchen has succeeded Professor Johann von Bokay in the chair of children's diseases at Budapest; Dr. Georges Bickel has succeeded the late Professor Gustave Humbert as extraordinary professor of propaedeutic medicine at Geneva; and Dr. Hermann Loeschke, director of the Pathological Institute of the Mannheim Municipal Hospital, has been appointed honorary professor at Heidelberg.

A MONUMENT to the late medical historian, Dr. Cabanès, will be dedicated in the cemetery at Gourdon (Lot) on September 1st.

A FURTHER series of brochures (Nos. 150 to 154) has been issued by the International Labour Office, the subjects being: carpets, hangings, and table covers; clerks and office employees; women's work; cresols, cresylic acid; and dimethylsulphate. These brochures, which are eventually to be published in volume form, can be obtained from the London office of this organization, 12, Victoria Street, S.W.1.

WE have received the first issue of *Archives de l'Institut Prophylactique*, a quarterly publication edited by Dr. Arthur Vernes. It contains original articles by the editor on syphilis.

conditions.

DR. HERMANN SAHLI, professor of special nosology and treatment, and director of the medical clinic at Bern, will retire this autumn.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Astrology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocrem Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

ACCOMMODATION IN UPPER EGYPT.

DR. ANTHONY DELMEGE (Weaverham, Cheshire) writes: I am anxious to hear of inexpensive accommodation—furnished flat or small hotel—in Cairo or neighbourhood, or indeed anywhere in Upper Egypt, for a patient with bronchitis and emphysema who will have to winter there.

TREATMENT OF LOCALIZED PULMONARY TUBERCULOSIS.

DR. J. GORDON HUME (London) writes in reply to the request of "W. J. D." (July 27th, p. 171) for advice in the treatment of a man, aged 27. [illegible]ces, and fatigue. He states: I [illegible] treatment with tuberculin b[illegible] I have administered many thousands of doses of tuberculin in the last few years, with the most satisfactory results, and I repeat what I have said elsewhere—namely, that tuberculin alone, when properly used, yields far better results than all other forms of treatment put together, including sanatorium and residence abroad. In every case where tuberculin has been used in time and the result has been failure, careful inquiry will elicit the facts that some form of tuberculin other than the original Koch's type has been used, and that some system of administration other than that taught by Dr. Camac Wilkinson has been employed.

SPONTANEOUS RUPTURE OF HYDROCELE.

"R. J. M." writes as follows in reply to Dr. R. Cock's question on July 20th (p. 130): In September, 1928, I was called urgently to attend a man, aged 56, who had collapsed while walking some distance from his home. On examination I found the left side of his scrotum enlarged to the size of a coco-nut; from the patient's history and my examination I diagnosed this a ruptured hydrocele. I inserted a trocar and cannula into the scrotum and drained away a pint of blood-stained fluid, leaving some of the fluid in the scrotum, which was absorbed in the course of a few weeks. When the fluid had drained away I was able to identify the left testicle with a hydrocele of small size. Six months later I examined the patient and found a large hydrocele on the left side, which showed no clinical evidence to mark its previous rupture; I tapped this in the usual way.

INCOME TAX.

Locumtenent and Assistant.

"X. Y. Z." asks for information on some questions the nature of which will be apparent from the following replies.

*** Where a professional man is definitely carrying on his profession by *short* term assistantship and locumtenencies we are of opinion that the correct schedule for assessment is Sched. D (professional profits) and not Sched. E (earnings of employment). On that basis the agency commission and costs of travelling are admissible expenses of carrying on the profession in a particular manner. Cash allowances for cost of living are assessable as part of the remuneration received. A reasonable proportion (representing professional as distinct from private use) of the running costs of the car *plus* depreciation at, say, 20 per cent. on a written-down basis, can be treated as expenses, but in that case the cash allowance received in respect of use of the car must be brought in as assessable to tax.

Basis of Assessment.

"W. B." qualified in July, 1927, and acted as an assistant for part of the period January to March, 1928, receiving £3½ for that work. He took over a practice as from July, 1928. What should be the basis of assessment of his earnings for the year to April 5th, 1929?

**** As there has been a change in the source of his earnings his liability for the year 1928-29 is determined by the actual amount of his earnings for that year. It is quite clear also that "W. B." must bring into the first year's account not only the cash received in that year but the value of the debts outstanding at the end of it. The liability for the nine months to April, 1929, will, of course, be three-quarters of the profit calculated for the year to July, 1929.

Motor-car Expenses—Private Use.

"J. R." has been informed that a medical man is entitled to deduct the whole expenses in connexion with his car, whether he uses it for private as well as professional purposes or not.

**** The governing provision is Rule 3 of Cases I and II, Sched. D, which runs as follows: "In computing the amount of the profits . . . to be charged no sum shall be deducted in respect of any . . . expenses not being money wholly and exclusively . . . expended for the purpose of the . . . profession." We have no doubt but that the courts would regard that portion of the motor expenses which are attributable to pleasure or other non-professional use of the car as coming within the prohibition of that rule. Further, we are of opinion that in calculating the amount to be excluded from the total expenses the basis adopted would normally be reckoned according to the mileage ratio of private to professional use.

Motor-car Transactions.

"G. T." bought a coupé in 1925 for £325 and replaced it in April, 1928, with a saloon costing £525. The local inspector of taxes claims to exclude £25 from the net cost of replacement as representing the improved capital value of a saloon as compared with a coupé. "G. T." points out that the amount of the capital expenditure on his car equipment is the same as before.

**** *Reliance on capital cost as the test cannot be regarded as safe.* When motor-car prices were rising the revenue authorities admitted that the whole of the (higher) capital cost represented replacement without improvement. The converse cannot successfully be resisted—that is, that improvement can be effected during a period of falling costs without an increase in the capital cost as compared with the former car.

"M. H." bought a new car in June, 1926, for £200 and sold it in June, 1928, for £65, buying another car for £120. What can he claim for 1927-28 onwards?

**** For 1927-28 and 1928-29 he could have claimed depreciation allowance at, say, 20 per cent. on the reducing value of the car, but that claim should be made when the return is lodged, and those claims are now apparently out of date. (The amounts on the 20 per cent. basis would have been £40 and £33.) The cost of replacement—that is, £120 − £65 = £55, is a professional expense of the year 1928, and will *pro tanto* reduce the amount assessable for 1929-30. For that year depreciation allowance should be claimed in respect of motor-car expenditure as *follows*: £200 − £65 − £55 + £120 = £200 at 20 per cent.—that is, £40.

"D. J. M." bought "A" car in 1924 for £225, and "B" car in 1927 for £155. In 1929 he sold both cars for (£10 + £60 =) £70, and bought "C" for £154. No "depreciation" allowance has been received in respect of the cars. What allowance is due?

**** The maximum allowance for the expense of car maintenance is the amount actually expended—that is, £154 − £70 = £84. If a second car is purchased it should be remembered that that car is also a replacement, and a further allowance will be due. This case illustrates the risks of not claiming depreciation allowance. Unless "D. J. M." buys a second car he will have lost substantially by not making that claim.

LETTERS, NOTES, ETC.

SIR WILLIAM OSLER'S LIBRARIES.

A Correction.

IN the footnote to the annotation published under the above heading in our last issue (p. 155) the price of the "Bibliotheca Osleriana" is given as 6s. This is obviously so absurd a price for such a work that we may hope that none of our readers have been misled into applying to the publishers for a copy at that figure. The correct price is 63s. net.

HERPES ZOSTER AND VARICELLA.

DR. IVAN H. MCCAW (Belfast) writes: In connexion with this subject I think the following is worthy of publication: A mother brought her family *of four children to my out-patient clinic* at the Belfast Hospital for Sick Children this morning. The eldest, a girl of 8 years, showed healing lesions of herpes zoster on the area of distribution of the left tenth thoracic nerve, the eruption having first appeared almost three weeks ago. This child had had an attack of chicken-pox during convalescence after scarlet fever while in the fever hospital three years ago. Two days ago her brother, aged 3½ years, developed a rash which, on examination, is chicken-pox. Yesterday two more brothers, aged 6 years and 18 months respectively, developed rashes, which also prove to be chicken-pox. This group of cases would suggest that the three brothers have been infected with chicken-pox from their sister's herpes zoster.

CONSULTATIVE COMMITTEES UNDER THE LOCAL GOVERNMENT ACT.

DR. I. HARRIS (Liverpool) writes: Your correspondent, Mr. E. W. Monnarrat (July 13th, p. 75) has made a misstatement. He says that the Liverpool Staffs Association "includes in its membership all those who are on the staffs of the local voluntary hospitals." Your correspondent must know quite well that there are three voluntary hospitals in Liverpool not included in the Association. In this respect the Heart Hospital is an instructive example. Its teaching material under one firm about equals the sum total of heart cases at the disposal of the eight physicians and seven assistant physicians of the four general hospitals. As a matter of fact, the number of students attending the hospital, considering its size, *by far exceeds* the number of students of the teaching hospitals. (It is temporarily closed to students owing to an accidental factor.) It is, however, not affiliated to the local school; therefore, it must be excluded, directly or indirectly, from representation on bodies such as the "Penny in the Pound" Council, which have nothing whatever to do with teaching! In order to safeguard their interests, there are four or five medical bodies on Merseyside in course of formation, which, no doubt, will receive recognition by the various lay committees interested in hospital work. Instead of showing a united front at this juncture, so vital to the interests of our profession, there will be four or five bodies acting independently and, to some extent, in opposition to each other.

CANE SUGAR IN THERAPEUTICS.

DR. C. HOLMES (Tongaat, Natal), with reference to Dr. C. G. S. Baronsfeather's note on the above subject (May 4th, p. 838), writes: If, indeed, "cane" sugar and "beet" sugar are indistinguishable chemically, it seems curious that therapeutic qualities should be possessed by the one and not the other. One must then assume that the action of cane sugar on heart muscle does not depend on an increased supply of glycogen, but on the presence of something in cane which is absent in beet. I do not know to what processes beet sugar is subjected in the course of its manufacture, but cane sugar is treated as follows: The cane juice is first treated with sulphur fumes, then lime. Following this it is boiled and treated with phosphoric acid. Lastly, it is filtered through animal charcoal. The sulphur is used for bleaching purposes; the lime, to precipitate impurities and to render the juice alkaline. Following boiling, phosphoric acid is added until the reaction to litmus is *slightly* acid. Is it possible that any delicate substance present in cane would remain unchanged throughout this procedure? It is true that boiling generally takes place at a low temperature at decreased pressure in order to hasten evaporation. The above process is applied to sugar manufactured in this district. I believe that in Cuba the treatment is somewhat different, and that sulphur and phosphoric acid are not used. Pure cane sugar should be white (colourless in solution), and require no bleaching with blue if properly cleaned. Brown sugar I have seen manufactured in Peru, but this certainly was not artificially coloured. Its brownness and stickiness are due, I think, to very slight *burning* in the boiling process carried out at atmospheric pressure. The "Demerara" referred to by Dr. J. Cameron (May 11th, p. 890) is probably a white sugar coloured purposely, but in that case the crystals would not be sticky or hold together. It would be interesting to learn whether the process of manufacture has any effect on the therapeutic qualities of sugar.

TRANSFORMER FOR SMALL SURGICAL APPLIANCES.

DR. E. M. R. FRAZER (Newhall, Burton-on-Trent) writes: With reference to the small *transformer* board for replacing dry batteries in the consulting room, which I described in your issue of May 11th (p. 857), I have had many inquiries regarding its use and where it may be obtained. Further inquirers may be glad to know that these boards can be obtained from Mr. Stone, 114, New Street, Burton-on-Trent.

LEAFLETS FOR PATIENTS.

FURTHER leaflets (Nos. 9, 11, 15, and 16) of the series of Instructions to Patients, prepared by Dr. T. P. B. Watson, have been issued by Messrs. H. K. Lewis and Co. The new leaflets give particulars of (*a*) how to prepare and apply poultices, (*b*) how to deal with constipation, (*c*) with pulmonary tuberculosis, and (*d*) general instructions for feverish cases, respectively. The price is 1s. per packet of 25.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 40, 41, and 42 of our advertisement columns, and advertisements as to partnerships, assistantships, and [illegible] at pages 38 and 39.

A short summary of [illegible] advertisements columns appears in the [illegible].

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

78. Site of the Primary Focus in Pulmonary Tuberculosis.

S. BANG (*Ugeskrift for Laeger*, May 2nd, 1929, p. 389) reviews the conceptions of the pathology of pulmonary tuberculosis, which, in the course of only three or four years, have been so changed that it is now considered a rarity for the disease to begin in the apex. When it does start here it is supposed to be of a comparatively benign character, usually clearing up without the help of sanatorium treatment. On the other hand, it is now assumed that the first demonstrable signs of the disease are most often to be found below the clavicle. To verify these teachings, which are associated with the names of Redeker and others, the author has made a study of 30 consecutive unselected instances of pulmonary tuberculosis in adults, many of which were early cases. In 19 the *x*-ray examination showed the most extensive processes to be infraclavicular. Begtrup Hansen has made a similar comparative study of the site of the exudative processes in 118 cases, and only in 29 did he locate these processes in the apex. In the remaining 89 cases these processes were scattered in other parts of the lungs, being found in the infraclavicular region in 45. In another series of 324 cases, in which cavities were found, the largest cavity was situated above the first rib only in 16 per cent., whereas it was found between the first and third ribs in 79 per cent. The practical results of the present-day conception of the pathology of pulmonary tuberculosis, so far as its diagnosis and treatment are concerned, are considered by Bang most important. Stethoscopically demonstrable signs in an apex do not necessarily imply that treatment is indicated, while the absence of stethoscopic signs over the apex are no guarantee of freedom from pulmonary tuberculosis. Indeed, he adds, no negative verdict must be given without the help of the *x* rays. The early cavities, which they alone can demonstrate, react very satisfactorily to one, and only one, treatment—an artificial pneumothorax. The absence of pleural involvement in these early cases contributes greatly to the success of this treatment.

79. Etiology of the Asthmatic Attack.

H. T. R. MOUNT (*Amer. Journ. Med. Sci.*, May, 1929, p. 697) remarks that the chief characteristic of asthma is the occurrence of paroxysmal attacks of respiratory dyspnoea, and that the suddenness of the onset and the course of the attack suggest, as the underlying mechanism, spasm of the bronchial musculature in response to some stimulus. It is generally accepted that the constrictor fibres to the bronchi travel through the vagi, and that there are cases of reflex asthma. Accepting these two factors, and that bronchial spasm plays a large part in the attack, it may be assumed that stimuli reach the lung and produce the asthmatic attack through the vagi. If certain cases of asthma are due to this cause, relief should result from a method of treatment which would interrupt the pathway of these stimuli. A series of animal experiments was performed to determine whether a physiological basis existed for a reflex mechanism in certain cases of asthma, and whether changes could be produced in the lungs of the animals similar to those found in asthmatic patients by various methods of stimulation of the vagi. The effects of section and evulsion of the bronchial branches of the vagi in a series of dogs were also studied. These tests established a [illegible] r the reflex nature of certain types of [illegible] in the lungs (bronchial constriction, bronchorrhoea, cellular infiltration, and emphysema) which resulted from stimulation of the vagi were similar to those seen in asthma. Since no untoward symptoms occurred in the dogs from section of the vagi, Mount suggests that in certain types of intractable asthma posterior mediastinotomy, with section of the bronchial branches of the vagi, using the extrapleural approach, might be considered.

80. Vascular Calcification in Diabetes.

L. B. MORRISON and I. K. BOGAN (*Journ. Amer. Med. Assoc.*, April 27th, 1929, p. 1424) report a study of the *x*-ray pictures of the legs and feet of 324 diabetic patients ranging in age from 2 to 81. The lower instead of the upper extremities were chosen for the study because the vessels of the leg show evidence of sclerosis earlier than those of the arms. Calcification was not always seen in the aorta even when the process was moderately advanced in the vessels of the legs; this was due partly, perhaps, to the fact that it is more difficult to detect calcification in the aorta. This investigation showed that the incidence and, as a rule, the degree of vascular calcification increases with age and with the duration of the disease. Evidence of calcification was present in 53 per cent. of the cases; in the third decade 6 per cent. of the patients had vascular calcification, and in the seventh decade 87 per cent. Advanced calcification was not found under the age of 40; it was noted in 21 per cent. of the cases. No case of gangrene occurred in patients younger than 40. Syphilis, dental infections, and arthritis appeared to play no part in the production of vascular calcification. The blood pressure in this series of cases increased with age, but not with the duration of the condition. The authors consider that radiology affords an accurate method of judging the presence of calcium in vessel walls, and is more reliable than clinical methods in the diagnosis of vascular calcification; they suggest that it might be helpful to insurance physicians. They conclude that diabetes mellitus is an etiological factor in the production of vascular calcification.

81. Rocky Mountain Spotted Fever.

R. R. SPENCER (*Journ. Infect. Dis.*, April, 1929, p. 257) states that this fever is an acute, specific, non-contagious tick-borne disease endemic in the north-western part of the United States, and closely resembling typhus fever clinically. The endemic area corresponds to the distribution of the tick, the virulence of the infection varying with the locality from 5 per cent. to 89 per cent. *Dermacentroxenus rickettsi*, a Gram-negative, pleomorphic, intracellular Rickettsia-like organism, is generally regarded as the causative agent. The average incubation period in man following natural infection by a tick bite is four to seven days, while in experimental animals the incubation ranges from twenty-four hours to ten days. The Weil-Felix reaction was present in most of the cases tested by Spencer. Prevention of the disease is threefold: (1) Tick or rodent destruction. Poisoned grain is used for the destruction of small rodents, and adult ticks are killed by dipping the domestic stock in water containing arsenic, washing soda, and pine tar. (2) Introduction of the tick parasite *Ixodiphagus caucurtei* for control of the spotted fever tick. (3) Inoculation with a vaccine prepared from infected ticks. The duration and degree of immunity conferred by vaccination vary greatly, and in some cases the immunity may not last longer than one season. There is no specific treatment.

Surgery.

82. Indications for Tonsillectomy.

A. FORSELLES (*Finska Läkaresällsk. Handlingar*, February, 1929, p. 101) prefaces a statistical analysis of the work of his hospital department with a review of the history of tonsillectomy in Europe and America. In the latter, within an unspecified period, 124 doctors were involved in judicial proceedings connected with tonsillectomies, 31 of which operations terminated fatally. In this series there were 9 cases of post-operative haemorrhage, 5 of abscess of the lung, 20 of injuries to the pillars of the fauces, and 16 in which the uvula was accidentally amputated. It is with this background of wholesale tonsillectomies, undertaken without definitely specified indications and involving legal sequels, that the author attempts to define concisely the indications for this operation. He concludes that it is justifiable in the case of (1) adults suffering from oft-recurring angina or chronic tonsillitis, with local or general symptoms; (2) malignant tumours, or benign tumours if these are more easily removed by tonsillectomy than by extirpation of the tumours; (3) sepsis of the tonsils; (4) children whose tonsillar symptoms are due to hypertrophy of the tonsils only in exceptional cases, and when tonsillotomy cannot be performed. Adults who have no tonsillar symptoms, and whose tonsils appear to be normal, should be allowed to retain them intact. In the ten-year period 1918–27, in the oto-rhino-laryngological department of the University Hospital in Helsingfors, 561 tonsillectomies were performed on 308 patients. In 55 cases the operation was limited to one side, whereas in 253 cases it was performed on both sides. 121 of these patients being operated on (each on two different occasions), and 132 having both tonsils removed at the same time. Only four of the patients were under the age of 10; seventeen were between the ages of 10 and 15. The youngest was 5 years old, the oldest 48. The only case that terminated fatally was that of a patient who, after being discharged from

hospital, was readmitted suffering from diphtheria, which necessitated tracheotomy, and was followed by pneumonia. There were twelve cases of rather severe haemorrhage at the time of operation, and nine of severe post-operative haemorrhage; one patient had abscess of the tongue. The indications for these tonsillectomies were recurrent attacks of quinsy in 72 cases, tonsillar plugs in 13, endocarditis or some other morbid condition of the heart in 24, polyarthritis in 48, nephritis in 6, lymphadenitis in 3, a fibroma of the tonsil in 1, meningitis in 1, and sepsis with empyema in 1 case. In the remaining 139 cases the patients suffered from relapsing angina or chronic tonsillitis.

83. Cancer of the Pancreas.

Dealing only with its semeiology, M. Roch (*Rev. Méd. de la Suisse Romande*, May 25th, 1929, p. 326) points out that the diagnosis of cancer of the pancreas is very difficult owing to the similarity of the symptoms to those of other conditions. It is essential to know the most frequent symptoms, and for this purpose the organ is considered as having three parts—the head, body, and tail. This classification is not absolute, since cancer, localized at first to one region, may successively involve all. Cancer of the head is by far the most frequent form, comprising 75 to 80 per cent. of the cases, and its symptoms have been ably described by Bard and Pic. The positive signs are a rapid cachexia, a bronzed icterus with faecal discoloration, distension of the gall-bladder, and sometimes pains and an epigastric tumour; the negative signs are the absence of ascites, of tumour of the liver, and of splenomegaly. The essential symptom is the icterus, while distension of the gall-bladder is also very characteristic and of great practical importance. This (the pancreatic-biliary) syndrome is the most frequent, and is due to compression of the common bile duct. In rare cases this compression does not occur, and this gives rise to a pancreatic-duodenal or pyloric syndrome which may simulate cancer of the alimentary tract. This can be differentiated by the presence of achlorhydria and occult or gross haemorrhages and by radiology. The symptoms of cancer of the body have been well described by Chauffard as a pancreatic-solar syndrome characterized by epigastralgias with very intense exacerbations and varied irradiations, gastric intolerance, and the presence of Einhorn's sign—increase of the pain in the dorsal decubitus, due to pressure on the retro-pancreatic solar plexus. This condition may be mistaken for tabes or gastric ulcer; differential points are the absence of signs of tabes, the cachexia, and the results of radiological and gastric juice examinations. Sometimes the tumour causes compression of the aorta; in these cases a pulsatile tumour, often with a systolic souffle, is felt on or a little to the left of the median line. This condition may simulate abdominal aortic aneurysm; the duration of the tumour, the absence of lateral extension and of retardation of the femoral pulse, rapid cachexia, and negative Wassermann reactions indicate malignancy. Cancer of the tail remains latent for a long period, slowly gives rise to signs of compression in neighbouring organs, and simulates tumours of the left kidney or spleen. The stomach is mostly affected. While cancer of the head compresses particularly the duodenum, and that of the body the lesser gastric curvature, cancer of the tail causes compression of the greater curvature, manifested by gastric pain, dyspepsia, and vomiting. X rays reveal a notch, causing almost an incomplete bilocunation, at the middle third of the stomach. This picture, variations according to position, the presence of peristalsis, and the rapid cachexia differentiate this condition from gastric cancer.

84. Injection Treatment of Varicose Veins.

M. B. Cooperman (*Med. Journ. and Record*, May 15th, 1929, p. 511) discusses the injection treatment of varicose veins from an experience of 500 injections given to 62 patients ranging in age from 22 to 67 years. In addition to the usual indications for treatment of the condition, such as unsightliness, pain, eczema, and ulceration, Cooperman considers that chronic hypertrophic villous synovitis of the knee-joint and other secondary degenerative changes, including hypertrophy, fibrosis, and osteo-arthritis, are often caused by the condition, and that sclerosing injections afford an effective remedy. The treatment is contraindicated in advanced diabetes, or if age accompanied by cardiac or renal degeneration, acute thrombophlebitis, and in cases in which the varicose veins are occluded or where there is lymphatic [illegible]. The only [illegible] the sclerosing [illegible] of 5 per cent. solution of sodium salicylate, the average total amount injected at [illegible] varying from 2 to 20 c.cm., the amount [illegible] injections a [illegible] solution of [illegible] but to counteract the cramp-like pains occurring after injection, normal salt solution freely injected round the vein after each puncture is advised. While cure is not claimed in all cases, and exceptional recurrences may occur, the proportion of successes is larger and relapses are less frequent than with the older surgical treatments.

85. L. Gaugier (*Presse Méd.*, May 25th, 1929, p. 686), in using the term "fragility" with reference to the veins, calls attention to the variety of response found to the injection of sclerosing solutions in the practice of Sicard's method for the cure of varicose veins. If it is arbitrarily admitted that the normal condition is to find a length of 6-8 cm. of a vein undergoing sclerosis, without any signs except those of an obliterative endovenitis, as the result of injecting 3 c.cm. of a 30 per cent. solution of sodium salicylate, then it must be admitted that in many cases there is a great variation in the direction of either hyper- or hypo-sensitiveness towards irritation, as measured by the extent of sclerosis resulting. In estimating the probable response of any patient's veins to treatment, Gaugier considers that the key to the question is to be found in the previous history. Wherever the circulation of toxins or bacteria in general diseases has been associated with thrombosis or phlebitis, a special "fragility" or hypersensitiveness of the venous walls to irritation should be suspected, and in such cases particular care should be exercised in choosing the strength and amount of the initial injection.

Therapeutics.

86. The Treatment of Hyperthyroidism.

D. Dautrebande (*Le Scalpel*, May 25th, 1929, p. 561) believes that rest is one of the principal treatments of hyperthyroidism, and cites the work of Kessel in this respect. This investigator placed fifty patients under the most favourable conditions of rest and quiet without any other treatment. Graphs are given which show that the results were as brilliant as those from surgery or radiotherapy. Dautrebande is not in accord with those who hold that iodine produces symptoms of Basedow's disease in cases of ordinary endemic goitre, nor with those who deny the prolonged action of this drug; he has found that prolonged effects can be obtained by increasing the dose each time metabolism rises after the initial drop. In refractory cases very high fractioning of the doses should be employed and the prescribed amount of iodine be given five or even up to twenty times a day. A commencing dose of 2 minims of Lugol's solution should be given five times, or in more severe cases ten times, a day; the solution contains 10 per cent. of iodine and 20 per cent. of potassium iodide. Guided by examinations of the basal metabolism, this fractioning is increased as is necessary; rarely is a larger amount than 30 minims a day required. By this method the gastric troubles caused by large doses of iodine are avoided. When the metabolism has been maintained at a minimum for several months, if the general state is good and particularly if there is no nervousness, the dosage can be decreased and finally discontinued for a period if a close watch is kept on the nutritive exchanges and the patient is guarded from emotional disturbances and infections. If a patient is refractory to even this treatment he should be put to bed and given very frequent small doses of iodine; a subtotal thyroidectomy may be performed during a lull in the nervousness. This treatment by rest, quiet, and fractional doses of iodine has proved most efficacious in maintaining a metabolic minimum, in restoring weight despite ambulatory treatment, and in creating physical conditions better able to tolerate more radical measures. This technique should be employed even in the most severe crises. If the goitre continues to exist despite thyroidectomy, it is the only possible treatment.

87. Plasmoquine in Malaria.

In a series of three papers R. Green (*Bull. Instit. Med. Res., Fed. Malay States*, 1929, No. 3) reports the results of treating cre-cent carriers and quartan malarial cases with plasmoquine compound, as compared with those resulting from quinine treatment alone. The daily dose of plasmoquine co., administered in tablets, was 0.04 gram of plasmoquine and 0.5 gram of quinine sulphate (8 grains of quinine sulphate). The results, in the author's opinion, justify the following conclusions. Plasmoquine appears to be more efficient than quinine in destroying the gametocytes of both *P. falciparum* and *P. vivax*. A dose of 0.04 gram daily in adult cases is an efficient gametocide, and, though this dosage is sufficiently free from toxic effects, continuous medical supervision is necessary in view of the narrow margin between the effective dose and that which may cause toxic symptoms. This dosage is sufficiently active against gametocytes to be effective in

sterilizing all but a very few crescent carriers in approximately twelve days. As each drug is effective in its own sphere, a combination permitting the convenient daily administration of 0.04 gram plasmoquine and 20 grains of quinine would be an advantage in treating cases of subtertian malaria which are also crescent carriers; in quartan malaria a similar dosage might be considered. No evidence was found in 96 cases that plasmoquine causes bradycardia. Contradictory results noted in subtertian and quartan cases do not permit the conclusion that plasmoquine causes a more rapid reduction in size of malarial spleens than does quinine, nor that abdominal pains after taking plasmoquine are due to rapid reduction in size of the spleen.

88. Mercurochrome in Biliary Therapeutics.

CONTINUING the previous work of Hill and Scott on the hepatic excretion of mercurochrome, L. MARTIN and J. H. HILL (*Amer. Journ. Med. Sci.*, May, 1929, p. 710) have studied the use of mercurochrome as a biliary antiseptic, as a means to visualize gall-bladders, and as a treatment in cholecystitis. Working with rabbits, Hill and Scott demonstrated that mercurochrome is excreted in large amounts by the liver, that the drug may be present in the bile in bactericidal quantities, and that artificially produced infectious of the gall-bladder could be controlled by intravenous injections of the dye. Some authorities agree with these findings; others contradict them. The present authors found that, after oral administration of mercurochrome to the point of salivation in thirteen individuals, the bile was never bactericidal or inhibitory and never contained visible traces of the dye; the treatment had no alleviating effects upon the symptoms in eight cases of cholecystitis. Following intravenous injections in man, the drug may be demonstrated in the bile siphoned out through a duodenal tube in eighteen to twenty-three minutes; this bile is bactericidal and contains mercury. Mercurochrome may be obtained also by duodenal drainage eighteen to twenty hours after intravenous injection; therefore it can apparently be stored in the gall-bladder. This latter bile is also bactericidal and contains mercury. Of eight patients with cholecystitis who received mercurochrome intravenously, three were not helped, but five were clinically cured and their bile specimens were sterile. The storage of mercurochrome in the gall-bladder results in a shadow being caused in *x*-ray films.

Neurology and Psychology.

83. Arterio-sclerotic Parkinsonism.

M. CRITCHLEY (*Brain*, April, 1929, p. 23) draws attention to a variety of Parkinsonism due to cerebral arterio-sclerosis. All gradations occur, from the mildest degree of hypokinesis and hypertonus (arterio-sclerotic rigidity) to forms barely distinguishable from classical paralysis agitans, but incomplete forms are more common. Arterio-sclerotic Parkinsonism may be classified into five clinical types: (1) early cases characterized by some immobility of expression and short-stepping gait; (2) cases forming part of the pseudo bulbar syndrome; (3) cases associated with marked intellectual defect; (4) pyramido-pallidal syndromes; and (5) cerebello-pallidal syndromes. Several clinically distinctive points between this condition and idiopathic paralysis agitans may be noted. The symptoms may commence suddenly in arterio-sclerotic cases, though an insidious onset is more usual. The progression is more rapid and may present abrupt exacerbations. The age of onset is approximately the same in the two conditions, but an unusually early or a very late age at onset suggests a vascular basis. In the arteriopathic cases tremor is usually absent, the muscles feel firmer to the touch, and the rigidity is often characterized by a superadded tendency to katatonia. Many arterio-sclerotic cases (those in Group 2) have "bulbar" signs and emotional incontinence, and in a large number there is also a more or less profound dementia. The presence of other focal cerebral symptoms (aphasic, apraxic, cerebellar, or pyramidal) indicates an arterio-sclerotic basis. Evidence of disease in the cerebral or peripheral blood vessels is present in the arterio-sclerotic varieties; the blood pressure is often high, but in the senile or decrescent types of arterial degeneration the tension may be low. The pathological appearances vary greatly in character and distribution; the essential features comprise lesions in the globus pallidus, and, to a lesser extent, in the substantia nigra, directly consequent on vascular disease. Pallidal lesions must not be regarded as solely responsible for the clinical appearances, for changes at other levels contribute to the rigidity. Thus, mental impairment, pyramidal disease, changes in the peripheral nerves and in the muscles, tendons, joints, and blood vessels of the extremities, all play a part in producing a hypertonic-hypokinetic syndrome. By isolating an arterio-sclerotic variety, support is given to the conception of Parkinsonism as a syndrome which may occur under numerous pathological circumstances. It is the site rather than the nature of the disease which produces the characteristic clinical picture.

90. Myasthenia Gravis.

A. QUERIDO (*Journ. Nerv. and Ment. Dis.*, May, 1929, p. 522) records a case presenting all the clinical characteristics of myasthenia gravis in which the pathological changes in the striated muscles, liver, lung, and kidney pointed to the condition being a general vascular disease defined as a perivasculitis chronica proliferans. The patient, a servant girl with a family history of lunacy, alcohol, and tuberculosis, involving several of her relations, had good health until she was 28, when she began to complain of extreme fatigue after slight exertion, double images, and attacks of collapse and dyspnœa, which gradually became worse until her death at the age of 35, after an illness of eight years. Necropsy showed cardiac degeneration, pericarditis, congestion of most organs, and a change in the aspect of the skeletal muscles. In addition to a marked distension of the capillaries, with occasional microscopic haemorrhages in nearly all the organs, the striped muscles, lungs, liver, and kidneys showed analogous microscopic changes, consisting of perivascular foci containing leucocytes, lymphocytes, plasmatic cells, fibroblast and ripe fibrous tissue, with traces of haemorrhage, and the walls of the vessel running through such foci were infiltrated with the same types of cells. The author, supported by evidence from the literature, regards the loss of muscle strength as a symptom of a general vascular disease caused by a chronic inflammation of the small vessels, which may occur in all parts of the body, thus affording an explanation of many hitherto puzzling accessory symptoms.

91. The Ocular Signs of General Paralysis.

J. V. ALVIM (*Rev. oto-neuro-oftalmol. y de cir. neurol.*, March, 1929, p. 104), who records 11 cases in patients aged from 26 to 58, states that in spite of the frequency of inequality of the pupils in general paralysis, it cannot be regarded as pathognomonic of this disease, since it is met with in numerous intoxications, infections, dementia præcox, cerebral tumours, and other psychoses, as noted by Mignot, Sérieux, and Marandel de Montyel. In addition to excessive contraction or dilatation, inequality in the size of the pupils, and changes in the reflex, ptosis, strabismus, diplopia, nystagmus, and amaurosis have been found in general paralysis. Apart from such causes as congenital ocular affections, influence of emotion, changes due to drugs such as morphine, eserine, scopolamine, and duboisine, a previous attack of iritis, and imperfect illumination, it should be remembered that rigidity of the pupils and the Argyll Robertson pupil are stigmata of syphilis and are the precursors of tabes or general paralysis. Although the Argyll Robertson pupil is not found in all cases of general paralysis, there is no doubt that its presence is in most cases a sign of syphilis of the cerebro-spinal axis, especially of the meningeal form, tabo-paralysis, or general paralysis.

Obstetrics and Gynaecology.

92. Cerebral Manifestations in Labour.

A. FRUHINSHOLZ and L. CORNIL (*Presse Méd.*, May 11th, 1929, p. 617) report sixteen cases of transient aphasia and hemiplegia occurring in parturient women, in order to show that in addition to cases where there is coexistent syphilitic disease of the brain, gross uterine sepsis, albuminuria, eclampsia, or valvular disease of the heart, there is a class of case where similar signs appear as the direct result of parturition itself. In their series all the manifestations were noted during the first three weeks after confinement, and in young and generally healthy women free from any of the complications mentioned above. The authors dissociate their views from those of Vinay, who published in 1894 an account of similar cases which he attributed to unrecognized lesions of the cardiac valves; they deplore also the tendency of writers of modern textbooks to regard all aphasic and hemiplegic incidents in parturition, from whatever cause, as being of equally grave import, one author having stated that the mortality in all cases was 47 per cent. With regard to etiology, the authors find that most patients were women between the ages of 20 and 30; of 15 cases where the parity was known, 7 were primiparæ, 4 confined for the second time, and 4 were multiparæ. In only three cases was labour normal; in the remainder there was some abnormality of placental insertion, forceps delivery, or other potential cause of minor degrees of sepsis. Two main varieties of cases are recognized. In the first the condition develops on the second

or third day without prodromal signs; these cases are essentially of transient duration, lasting from a few hours to two or three days. In the second variety there is more commonly a gradual onset between the seventh and twenty-fifth days, and the condition is of longer duration. In 14 of the 16 cases recorded there was a right-sided hemiplegia of varying severity, with all the classical signs except for the absence of Babinski's reflex—a point in favour of a transitory lesion of the cerebral cortex. The appearance of Jacksonian movements of the right arm, in 4 cases, suggests to the authors that the lesion was a cerebral oedema, while the occurrence in others of subjective paraesthesia without any pain is regarded as proof of the lesion being cortical rather than deep. In 13 cases aphasia was associated with right hemiplegia. In one case aphasia occurred as the sole symptom, and in 3 there was no aphasia. When present it was usually of the Broca type, both expression and comprehension being affected. The prognosis, judging from this series, is relatively good. There was one death from pulmonary embolism, but in the majority the condition cleared up completely in a few days to a few weeks; in only one case was there a residual paralysis after three months, while in 4 patients further confinements were without complications. With regard to pathology, the authors admit that nothing can be stated with certainty, but they note that the selective period of occurrence (mostly from the ninth to the seventeenth day) is the same as that for embolic accidents; they have also been struck by the fact that in their small series two cases of phlegmasia alba dolens were found, and that this condition is seen most often in the same type of patient. Among other hypotheses to explain the condition, one is the existence of a patent interauricular septum in association with minute haemic or bacterial emboli of venous origin. The authors are inclined to support this theory of causation because of the common localization of the lesion to the left side of the brain.

93. Streptococcal Antitoxin in Puerperal Fever.

A. F. LASH (*Amer. Journ. Obstet. and Gynecol.*, March, 1929, p. 297) records his observations on 57 women in various stages of puerperal fever treated by a new concentrated streptococcal antitoxin; 20 were cases of uncomplicated acute endometritis and metritis, 20 of acute endometritis and parametritis, 10 of pelvic peritonitis and generalized peritonitis, 30 of parametritis and thrombophlebitis, and 4 of embolic pulmonary complications. Lash's conclusions were as follows. Small doses of concentrated antitoxin producing favourable clinical results without immediate reactions indicated a specific rather than a non-specific action. Further evidence of this specific action was adduced by the fact that with the increasing potency of the serum correspondingly smaller doses were used with equivalent results. The large amounts of serum employed at first were probably superfluous, as the only guide then used was fever rather than the condition of the patient. Immediate reactions were uncommon, and serum sickness only occurred after large doses. The antitoxin did not produce any irritating effect upon the kidney or any other organ. As this antitoxin is comparable in its efficacy in the treatment of puerperal fever to diphtheria, scarlet fever, or tetanus antitoxin, a woman developing symptoms of puerperal fever should receive it within thirty-six to forty-eight hours of the onset. In an advanced stage it is practically useless. Comparison of mortalities in the group of patients receiving antitoxin (32 per cent.) and control group (61 and 61 per cent.) is evidence of the therapeutic value of puerperal fever streptococcal antitoxin.

94. Caesarean Section in Infected Cases.

A. PAGEZ (*Zentralbl. f. Gynäk.*, March 23rd, 1929, p. 726) compares the merits and demerits of Porter's and Sellheim's operations in cases in which, although there is indubitable clinical evidence of infection of the mother, natural delivery is impossible. He contrasts an operation with the mortality of the living or dead foetus [illegible] per cent. mortality of Porter's operation [illegible] these seven cases hitherto recorded [illegible] Porter's operation as illusory. Sellheim's [illegible] Porter records a further successful example, consisting [illegible] which was described twenty years ago, and of [illegible] operation [illegible] the past [illegible] the anterior wall of the [illegible] patient in the horizontal position [illegible] the uterus [illegible] and the wound [illegible] by [illegible] Porter's [illegible]

Pathology.

95. Secondary Echinococcosis.

H. DEW (*Journ. Coll. of Surg. of Australasia*, March, 1929, p. 337) describes the structure of a simple hydatid cyst, and states that if one be punctured or ruptured under aseptic conditions death of the parasite does not invariably follow. The parasitic cells in many cases are so persistent that the germinal elements give rise to a fresh local or generalized series of cysts, the phenomena being best described as secondary echinococcosis. In the case of multiple cysts, it is probable that they are secondary. Dew believes that secondary cysts are mainly derived from the relatively undifferentiated scolices rather than from the mature type, and that daughter cysts, brood capsules, scolices, and germinal membrane can all give rise to secondary cysts that may ultimately become fertile. Four types of this condition are discussed: localized secondary echinococcosis; peritoneal and pelvic echinococcosis; pleural; and metastatic echinococcosis. A good example of the localized type is seen in cysts of the subcutaneous or muscular tissues, in which either direct mechanical trauma or violent muscular contraction leads to the shedding of germinal elements into the tissues. Post-operative recurrence in the original cyst, in the scar, or in the depths of the operation field constitutes another type. Secondary cysts in the peritoneum are the most familiar type, and are always due to leakage from a primary abdominal cyst, which is usually situated in the liver. The scolices may remain localized near the liver, giving rise to multiple perihepatic cysts, but as a rule the lower quadrants of the abdomen and the pelvis are their favourite sites. These cysts are of slow growth during a latent period of five to fifteen years. Following intrapleural rupture of a cyst, a simple or valvular pneumothorax is usually seen. These secondary cysts may be localized by adhesions or become generalized throughout the cavity. Metastatic secondary cysts are the rarest type, may occur in the lungs, brain (the commonest), heart, spleen, and kidneys, and are always due to an intravascular rupture of a fertile simple cyst. Such rupture may occur into the venous circulation, either into the peripheral veins or into the arterial stream, when it always involves the heart, or into the arterial veins or into the right side of one of the left cardiac chambers.

95. Clive's Serum Test for Syphilis.

F. CANTANI (*Ref. Med.*, April 27th, 1929, p. 564) has repeated the technique of Clive, who, by his acetic anhydride method of testing the serum for syphilis, obtained in a series of 574 serums only 80 that were not in agreement with Wassermann test results. Two cases gave positive Wassermann reactions and negative Clive ones, while 78 with negative Wassermann reactions were positive according to the Clive test. But, after excluding from the last group those cases which were undoubtedly or probably syphilitic, Clive concluded that his method only gave an erroneous positive result in eighteen non-syphilitic cases, equivalent to the small error of 3.35 per cent. Cantani's observations, however, on 193 serums were as follows. Out of 82 serums positive according to the Wassermann test 78 were similarly positive by the Clive test, but the Clive reaction was positive also in no fewer than 93 of the remaining 108 serums in which the Wassermann reaction was negative. These results show an agreement of 95 per cent. for the positive group, but only a 16.6 per cent. agreement for the negative group. Cantani concludes that Clive's test is not applicable to the serum diagnosis of syphilis.

97. The Reaction of Brucella abortus and Brucella melitensis to Certain Aniline Dyes.

S. SAITTA (*Giorn. di Batter. e Immunol.*, April, 1929, p. 307) has examined the effect of certain aniline dyes on the growth of seven strains of *Br. melitensis* and eight strains of *Br. abortus*. The dye was incorporated in an agar medium; the tubes were inoculated with the same number of organisms; and readings of the amount of growth were taken after two or three days or so. It was found that on agar containing 1 in 50,000 gentian violet all but one of the *abortus* strains multiplied freely, while only two of the seven *melitensis* strains grew well. The differentiation of the two groups of strains was rather more marked on agar containing 1 in 25,000 basic fuchsin. The best differentiation, however, was obtained with 1 in 25,000 malachite green; on this medium all of the *abortus* strains developed, while only three of the *melitensis* strains grew at all, and then only in discrete colonies. The author does not maintain that the use of aniline dyes will enable one to distinguish with certainty between the two organisms; but he does assert that the difference in relation between the two organisms is sufficient to show that they cannot be considered as identical.

THE "JACK SPRATT" CHILD.

"Jack Spratt could eat no fat"

Nervous children, the "Jack Spratts" of the nursery, digest fat badly. This fact has been emphasised recently by such eminent authorities as Still, Cameron & Osman.

Modern conditions of life make great demands on the nervous systems of such children. They are more highly strung, react more readily to emotional stimuli, and this strain is often reflected in digestive difficulties, such as cyclical vomiting, loss of appetite, constipation and bilious attacks.

It has been repeatedly demonstrated that these children cannot tolerate a diet rich in fat, and that whatever fats are to be dealt with must be metabolised in an excess of sugar. An insufficiency of sugar results in the production of ketone bodies and consequently ketosis. An excess of fat is split up in the bowels and neutralised by the valuable calcium and magnesium salts of the milk, which are subsequently excreted in the familiar pale, dry, and crumbling stools.

To meet the needs of this type of infant the manufacturers of "Cow & Gate" Milk Foods have provided a

HALF CREAM

PACKED IN A BLUE TIN

Cow & Gate Milk Food

PACKED IN A BLUE TIN

This food has the following composition:—

	Dry Food	Reconstituted (1 part in 8 parts of water)
Fat	15.5	1.7
Proteins	20.0	2.2
Lactose	58.0	6.4
Mineral Matter	4.5	0.5

Half Cream "Cow & Gate" has been used in the large class of "nervous dyspepsias" of infancy with eminently satisfactory results, proving invaluable as a food during periods of fat intolerance so noticeable in the "Jack Spratt" type of infant.

The manufacturers will gladly supply samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

EATAN

Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-irritant.

Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.

Issued in 2/6, 4/-, and 12/- bottles.

Special Terms to Hospitals.

Test sample and literature sent post free on application to:

COLLENDER'S SPLINTS

(Patented in the Leading Countries of the World)

An evolution of the Thomas Splint—all the advantages of the Thomas Splint are preserved, with many important improvements, additions, and modifications.

They are supplied in strong fitted case, and enable 10 fractures simultaneously to be put up in any position obtainable by Thomas arm or leg Splints.

They provide the most modern methods of accurate extension, and safe transport of the patient is assured. Complete splints suited to limbs of any dimensions can be constructed in a few minutes from the component parts.

All members are interchangeable, standardised, numbered, and replaceable. They are made of Duralumin, which is untarnishable, exceedingly light in weight, and of great tensile strength. They can be immersed in sterilizing fluid without injury and can be used repeatedly.

Collender's Splints will be found invaluable for Hospital Emergency work and particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most *modern treatment of Mental and Nervous Disorders*. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private *bathing house on the seashore*. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56. Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an *eminence* a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

(University of London.)

Tropical Medicine and Hygiene.

The School provides two courses yearly, each of 20 weeks. The next courses commence on September 30th, 1929, and February 3rd, 1930.

Diploma in Public Health.

The course of study in Public Health, covering a period of 12 calendar months, commences on September 30th, 1929, and is so designed that students wishing to do so can proceed to the new academic dilpoma instituted by the University of London.

The inclusive fee of 50 guineas will cover the cost, not only of the ordinary lectures and demonstrations, but also of the necessary practical work in public health departments and instruction in infectious diseases, etc.

Diploma in Bacteriology.

The course of study, covering one academic year, commences in October.

Special advanced courses of study in various branches of Medicine and Science are given by the Professors and other teachers on the staff of the School.

Applications for information as to the above courses and other special advanced courses of study should be addressed to the Secretary, Keppel Street (Gower Street), London, W.C.1.

URSULINE CONVENT, WESTGATE-ON-SEA, KENT.

A High Class BOARDING SCHOOL is conducted here by the Ursulines of the Roman Union.

The School is situated in its own extensive and beautiful grounds, in a neighbourhood renowned for its bracing and healthy air.

Pupils are prepared for the Cambridge Local and Royal Academy of Music Examinations.

On leaving school pupils may be transferred to houses of the Order in France, Italy, Austria, and other countries.

Terms on application to the Reverend Mother Prioress.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON).

Refraction and the Ordering of GLASSES

taught by Practising Ophthalmic Surgeon in London. £8 8s for 10 lessons.—Address, No. 125, B.M.A. House, Tavistock Square, W.C.1.

COLONIAL MEDICAL SERVICES.

Vacancies exist at present for MEDICAL OFFICERS in:—

(*a*) THE WEST AFRICAN MEDICAL STAFF.

(*b*) THE MALAYAN MEDICAL SERVICE.

QUALIFICATIONS.

Applicants must be British subjects of European parentage and between 22 and 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held hospital or public health appointments, or who have special knowledge of anæsthetics, radiology, surgery, medicine, ophthalmology, gynæcology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc.

COURSES OF STUDY.

Selected candidates will be required to take a special course of study in tropical medicine and hygiene commencing in October, either at the London School of Hygiene and Tropical Medicine or at the Liverpool School of Tropical Medicine, or at the University of Edinburgh, before taking up their appointments. Tuition fees will be paid and an allowance granted by Government subject to certain conditions.

Further particulars and forms of application may be obtained, on application in writing, from the PRIVATE SECRETARY (APPOINTMENTS), COLONIAL OFFICE, 2, Richmond Terrace, Whitehall, London, S.W.1.

ROYAL AIR FORCE MEDICAL SERVICE.

A limited number of candidates will be selected for Commissions as MEDICAL OFFICERS in the Royal Air Force in September, 1929.

The next course of instruction for Medical Officers on joining will begin on October 1st, 1929.

There will be no entrance examination, candidates being appointed by selection. Candidates wishing to submit applications should apply for full particulars as to the conditions of service and emoluments and forms of application to the *Secretary, Air Ministry (D.M.S.), Adastral House, Kingsway, London, W.C.2.*

They should be prepared to attend for interview and medical examination in London about the middle of September.

Middlesex Hospital Medical SCHOOL (UNIVERSITY OF LONDON), London, W.1.

PHYSIOLOGY.

A SECOND DEMONSTRATOR (not necessarily medically qualified) is required for the Department of Physiology. He will be expected to carry out research under the direction of the Professor, and ample time and facilities will be afforded for this work.

The appointment will be for one year in the first instance, and the holder will be eligible for re-appointment on the recommendation of the Professor. Initial salary £250 per annum. Applications, together with copies of testimonials, should be sent to the School Secretary, Middlesex Hospital, London, W.1, not later than September 1st, 1929.

Glasgow Asylum Service.

JUNIOR ASSISTANT MEDICAL OFFICER (male) wanted for the GOVAN DISTRICT ASYLUM. Previous asylum experience unnecessary, but preference will be given to one who has engaged in pathological work or has been House Physician. Ample opportunity afforded for research. Salary to commence £525 per annum, with board, lodging, and laundry. Full particulars on application to the Medical Superintendent, Hawkhead Asylum, Glasgow, S.W.2.

University of Sydney.

The Senate invites applications from gentlemen qualified to hold the BOSCH CHAIR OF SURGERY, the duties of which commence on March 1st, 1930. The salary is £2,500 per annum, without Superannuation rights. Applications (8 copies) should reach the undersigned by October 19th, 1929, but the University reserves to itself the right to invite any person to the Chair. A memorandum giving further particulars may be obtained on request.

Hackney Union.

APPOINTMENT OF MEDICAL SUPERINTENDENT OF THE HOSPITAL AND CHIEF MEDICAL OFFICER OF THE UNION.

The Hackney Board of Guardians invite applications from duly qualified gentlemen for the post of Medical Superintendent of the Hackney Hospital, Homerton, and Chief Medical Officer of the Union.

The Hospital accommodation is 800 beds, and there is a completely equipped Clinical Laboratory, also X-ray, Massage, Electro-Therapeutical, and Out-patient Departments.

The Hospital is recognized as a training school by the General Nursing Council for England and Wales and the Central Midwives Board.

Applicants must not be over 45 years of age. They must have held the appointment of House Physician or House Surgeon in a Public General Hospital or a Resident Medical appointment equivalent thereto, and had experience in the administration of a Public General Hospital or Poor Law Infirmary, and also had experience in operative surgery.

The combined salary is at the rate of £1,000 per annum, with meals when on duty, valued at £45 10s. per annum. In addition, there is a money allowance in lieu of other residential emoluments of £125 per annum, while non-resident.

All Lunacy fees are to be regarded as included in the salary. The officer, however, will be allowed to retain Vaccination and certain other fees (*without guarantee from the Guardians*), which last year amounted approximately to £300.

The appointment will be subject to the *approval of the Ministry of Health and to the* provisions of the Poor Law Officers Superannuation Act, 1896.

Canvassing the Guardians, directly or indirectly, will *disqualify.*

Forms of application and full details may be obtained from this office.

Completed forms of application must be returned by 10 a.m. on Monday, August 5th.

By Order,
E. W. HARBOUR,
Clerk to the Guardians.

Clerk's Offices,
Hackney Union,
2, Sidney Road,
Homerton, E.9. July 24th, 1929.

Urban District of Shipley.

Applications are invited from duly qualified gentlemen for the appointment of MEDICAL OFFICER OF HEALTH of the Urban District, subject to the provisions of the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926.

The gentleman appointed will be required to perform all the duties imposed on a Medical Officer of *Health, to act as* School Medical Officer, Superintendent of the Maternity and Child Welfare Centre, and to carry out all such duties as the Council may, with the consent (if necessary) of the Ministry of Health, from time to time direct.

He must reside in the district, and devote all his time to the duties of the office, and must not engage in private practice.

The appointment will be subject to the approval of the Minister of Health, and will also be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

The salary to cover all the duties specified above will be £800 per annum.

Applications, stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials, should reach the undersigned not later than August 10th, endorsed "Medical Officer."

Canvassing, either directly or indirectly, will be a disqualification.

H. BARNES,
Clerk to the Council.

Council Offices,
Shipley.
July 25rd, 1929.

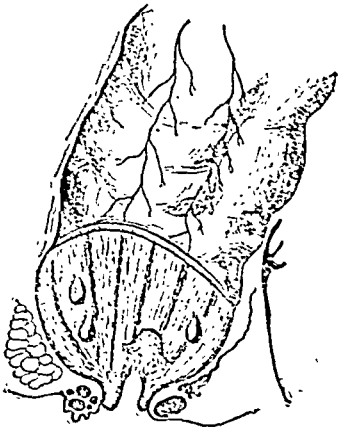
The Haemorrhoidal Circle



Internal and external hæmorrhoids resulting from pressure upon the blood vessels and obstruction of the circulation in the rectum.

DISTENTION of the rectum from painful defæcation—pressure on the rectal blood vessels — impeded circulation — hæmorrhoids. Cathartics to relieve the constipation —irritation of the mucous membrane and the existing hæmorrhoids — pain — possible anal fissure — cessation of purging—constipation.

Such is all too frequently the vicious circle of dyschezia and hæmorrhoids, a combination which requires appropriate local treatment and a bowel corrective that will not irritate.

AGAROL Brand Compound, the original emulsion of mineral oil, agar-agar and phenolphthalein, is pre-eminently indicated for the correction of the vicious circle.

AGAROL Brand Compound lubricates, therefore prevents irritation by friction; it segments and softens the fæcal mass, and thereby prevents possible excessive strain in the expulsion of it; it stimulates the peristaltic force without the shock of cathartics.

A liberal quantity sent to physicians on request.

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:

alkalies and alcohol, no oil leakage; no griping or pain; no nausea; not habit forming.

HORMOTONE
BRAND

in disorders of the

CATAMENIA

and the

MENOPAUSE

Hormotone supplies the physiological stimulus to the endocrine glands, whose functional activity determines the normal catamenial flow.

When these internal secretions begin to fail at the period of the menopause, Hormotone acts both by substitution and homostimulation.

Dose: One or two tablets three times daily.

Toast *and* Toast Racks superseded

The "RYVITA RACK" has displaced the old-time toast rack

Every day, more and more people are discovering how much more delicious, how much better than toast is "Ryvita Crispbread," the wonderful daily bread of Sweden.

"Ryvita" is made of rye—and nothing but rye—the only cereal from which this the true Crispbread can be made. The first people in this country to eat it were those most highly qualified to judge food values—doctors, dentists, and dietetic experts. "Ryvita" reached the multitude by way of the specialist, thus—despite envious imitators—establishing here "The Ryvita Crispbread Habit."

Eaten as your Daily Bread—"Ryvita," the Veritable Bread of Life, helps to make indigestion, constipation, malnutrition, and obesity unknown. Yet . . . so unique is this wonderful bread, that it is practically impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade. Notice how it sustains without cloying . . . how it gives you an exhilarating sensation of well-being and clear-headedness . . . how you work better, play better, and feel better on "Ryvita."

You will then understand why the old toast rack is now the "Ryvita" rack.

Send a postcard for generous FREE Sample to the Ryvita Company, 417, Ryvita House, 96, Southwark Street, London, S.E.1. Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb., 10d.

Makes you fit— RYVITA CRISPBREAD keeps you slim

RECENT ADVANCES IN CARDIOLOGY

By C. F. TERENCE EAST, M.D., F.R.C.P., Junior Physician, King's College Hospital; and C. W. C. BAIN, M.C., M.B., Assistant Physician, Harrogate Infirmary.

NOW READY. 2 Coloured Plates, 181 Text-figures. 25s., postage 9d.

STONE IN THE URINARY TRACT

By H. P. WINSBURY WHITE, M.B., Ch.B., F.R.C.S., Hon. Assistant Surgeon, St. Paul's Hospital for Genito-Urinary Diseases.

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1

". . . the detection, a large part of the treatment, and some measure of the prevention must continue to be the concern of the general practitioner."

From the "British Medical Journal," June 1st, 1929, reviewing:

A TEXT-BOOK OF PULMONARY TUBERCULOSIS

By R. C. WINGFIELD, M.B., B.A.Oxon., F.R.C.P.,

Late Physician in charge of the Tuberculosis Department, St. Thomas's Hospital; Medical Superintendent, Brompton Hospital Sanatorium, Frimley.

Demy 8vo. xvi + 401 pages. 92 figures. 52 plates. **31/6 net.**

Considerable attention—both official and general—is being devoted to the subject of pulmonary tuberculosis. National tuberculosis services have been inaugurated, from which the practitioner may obtain the assistance and advice of men specially trained in observation of the disease, and who, by intensive study, may ultimately find some solution to the problem. These services are rapidly increasing in efficiency; but unfortunately there are some less satisfactory than others, in which case (once again quoting from the pages of the "British Medical Journal"): **"the practitioner will be well advised to turn to such a book as that of Dr. Wingfield, from which he will obtain a sane estimate of what can, and what cannot, be done for a tuberculous patient."**

Dr. Wingfield's book is not a résumé of other workers' opinions and publications, but a systematic and lucid survey of the disease—embodying the results of many years' experience and research. Many of the books hitherto published are either too exhaustive or too short. "A TEXT-BOOK OF PULMONARY TUBERCULOSIS" is between the two. It is obtainable from all medical booksellers and libraries, or direct from the publishers:

CONSTABLE & CO. LTD. 10 & 12 ORANGE ST. LONDON W.C.2

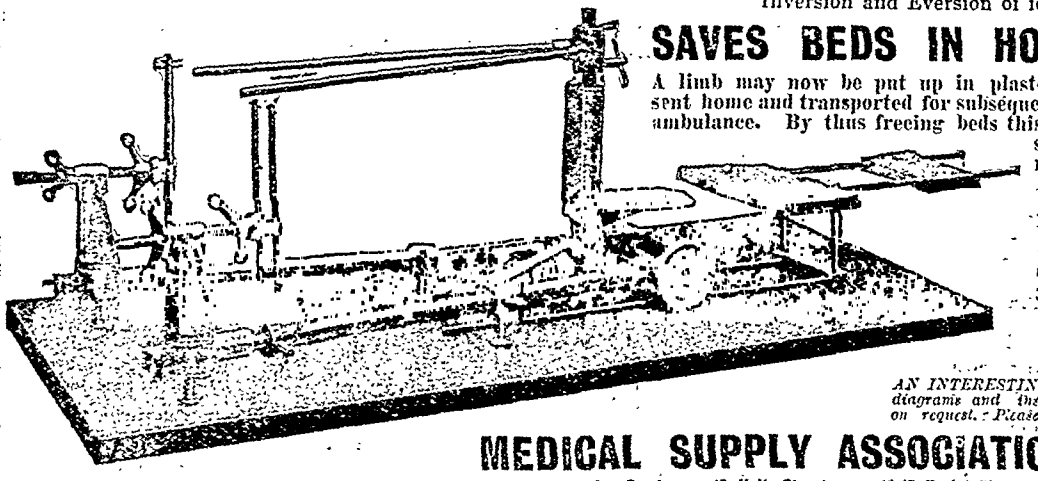
93, Regent St., London, W.1, near Piccadilly.

An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:
Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE. *Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.*

MEDICAL REPORTS. *Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.*

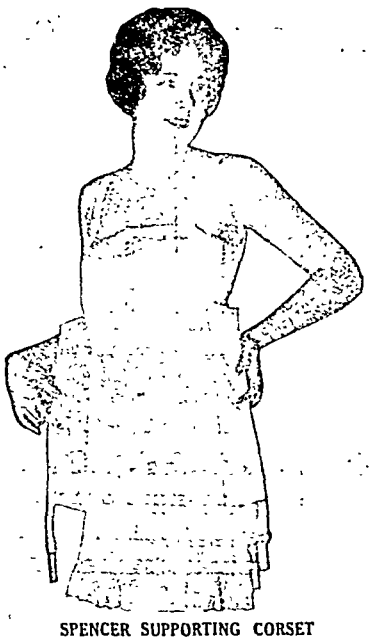
A Surgical Support Can Be Effective and Yet Be Light in Weight, Comfortable and Beautiful

Physicians and surgeons themselves, to say nothing of their women patients, demand surgical supports these days which are not only effective but are also light in weight, and comfortable in cut and fit.

Twenty years ago surgical supports were heavy. This was true even of Spencer supports. Changes in women's habits of life have led gradually to a demand for greater comfort and freedom in surgical supports as well as in "style" corsets. Physicians and Spencer designers co-operating in numerous experiments, know now that a surgical support can be effective and yet be light in weight and pleasant to wear.



SPENCER SUPPORTING CORSET
Front opened and held back to show inner supporting section

Because the Spencer support is individually designed for the patient who is to wear it, it will remain in position on the figure, and do the work required of it, even though it is so comfortable that the wearer is hardly aware that she has it on her body.

Physicians experience but little difficulty in obtaining the co-operation of patients for whom Spencer supports are prescribed because the garments can be really beautiful, and serve all fashion requirements, and yet do the work that the physician demands of them.

You can see, and have demonstrated to you, all kinds of Spencer supports—those for maternity and postpartum wear, for hernia, enteroptosis, movable kidney, and sacro-iliac strain.

In your own city or town, at any time, you can have the co-operation of a Spencer corsetière who is trained to take measurements accurately, to describe posture and figure exactly, to adjust garments properly, to give intelligent after-service, under the physician's instructions.

We will gladly send you booklets on the uses of Spencer supports.

Suit the Appliance to the Season.

OCTOBER
NOVEMBER
DECEMBER
JANUARY
FEBRUARY
MARCH

Practically everybody discards heavy underclothing for lighter weight during the summer months, yet patients doing this frequently retain their Winter appliance, being unaware of belts of more porous texture.

The ordinary belt when worn during the Summer induces excessive perspiration, thereby shortening the life of the appliance.

Warmer days call for lighter clothes—why not for more suitable appliances also?

Patients will welcome eagerly the added comfort and complete freedom of movement for outdoor exercises afforded by

BUST OF HOMER

Intestinal Atony

For establishing a natural daily evacuation of the bowels "Cristolax", offers a desirable form of treatment in every respect. It is not habit-forming and obviates the need of purgatives, which often produce harmful results.

Under the use of "Cristolax" tone is given to the digestive process, inspissation to the fæces prevented and a healthy condition of the bowel maintained. Further, no leakage of oil occurs from the rectum, as usually happens when liquid or semi-liquid forms of paraffin are used.

Briefly described, "Cristolax" is a digestant, lubricant, and bowel eliminant. It is in the form of fine, granular crystals, presenting an attractive appearance. The taste is so very palatable that the product has been described as being "as nice as sugar-candy."

HUMANISED MILK

PREPARED WITH

Peptogenic Milk Powder

Humanised Milk prepared with PEPTOGENIC MILK POWDER is remarkably like mother's milk in all particulars: in physical properties, in colour and taste, and in the percentage of nutritive constituent; in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.

Humanised Milk prepared with PEPTOGENIC POWDER has simply the normal digestibility of mother's milk: it is not too easily or unnaturally digestible, and contains no aid to digestion. It affords a complete substitute for mother's milk during the entire nursing period.

PEPTOGENIC MILK POWDER—the original preparation offered for humanising cow's milk in the home—has been on the market for over 40 years. Supplied in two sizes.

Originated and Manufactured by
Fairchild Bros. & Foster (Inc. N.Y.)
NEW YORK, and 67, Hellen Viaduct, LONDON, E.C.1.

Agents:
Burroughs Wellcome & Co.,
LONDON, SIDNEY, and CAPE TOWN.

BOOTS PRODUCTS

Acriflavine (BOOTS)

One of the most potent of modern antiseptics, physiologically pure and extremely soluble in water. Acriflavine (Boots) kills organisms in a concentration of 1 in 100,000. Its potency is actually increased when brought into contact with serum. Now recognised as the routine preparation for irrigations in the treatment of gonorrhœa. Ideal for suppurating wounds and septic conditions of all kinds.

Acriflavine (Boots) is supplied in 5 gm. and 20 gm. bottles, and in tablets (1.75 gr. and 2.187 gr.).

Neutral-Acriflavine (Boots) is specially prepared for internal use in the form of enteric-coated tablets, and also for hypodermic or intravenous injections.

Neutral-Acriflavine (Boots) is supplied in 5 gm. and 20 gm. bottles, in tablets (1.75 gr.), and in enteric-coated tablets (½ gr.).

SALINE NOTE
No. 2.

A Natural Aperient

Pleasant to take—harmless even in large doses—free from strong purgatives.

Wills' Salt is an effervescent saline which increases the fluid content of the bowel and promotes increased peristalsis. It neutralizes excessive acidity, thus eliminating the chief cause of gastric disturbances and liver troubles. The evacuation is painless and complete and there is no tendency to gripe.

Wills' Salt is a well-balanced combination of the best saline cathartics—easily tolerated by all.

Testing tin on application.

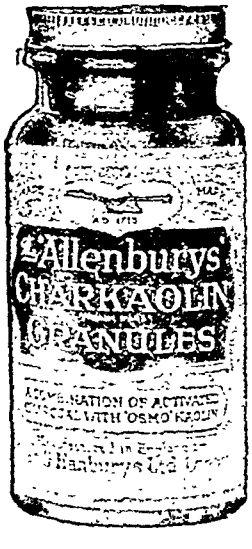
The 'Allenburys'



'CHARKAOLIN' GRANULES

A Combination of Highly Activated Charcoal with 'Osmo' Kaolin

'Charkaolin' is a new and highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of 'Osmo' Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. 'Charkaolin' is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

ALLEN & HANBURYS Ltd., Bethnal Green, E.2

Acriflavine

'B.D.' Brand

Acriflavine 'B.D.' Brand has held its supreme position in the field of antiseptics on account of its high bactericidal potency, which is actually increased in the presence of serum.

Acriflavine 'B.D.' Brand was used originally in the treatment of wounds. More recently, its valuable properties have been applied in other directions: for example, in gonorrhœa, which responds particularly well to lavage with this antiseptic; further, it has proved of remarkable value in dermatology, in dentistry and in ophthalmic surgery, whilst in phthisis and in tonsillitis Acriflavine 'B.D.' Brand has given extremely encouraging results.

Issued in powder, in tablets and in solution

BRAND'S ESSENCE OF BEEF for INVALIDS

has enjoyed the confidence of the medical profession for over 90 years. A nourishing stimulant that demands the least amount of energy in the process of assimilation and increases the means of defence by raising the powers of resistance.

Mark it in your memo book

Brand's essences are scientifically prepared, in jelly form, from the finest English meats, and contain upwards of eleven per cent. of proteid. The nourishing and stimulating properties are IMMEDIATELY ABSORBED, without residue, in the alimentary canal. No time is lost in process of assimilation. No work entailed by the digestive organs. Absolutely pure. Contains no gelatine, colouring, or preservatives. Good for young and old alike.

BRAND'S ESSENCE OF CHICKEN

contains the same nourishing and stimulating properties as Brand's Essence of Beef, and for over 90 years has been recommended by the medical profession when required by prevailing conditions.

Sold by Chemists Everywhere.

Prepared by

BRAND AND COMPANY LTD., LONDON, S.W.8.

Oranges preserved this way retain all their healthfulness

Frank Cooper's "Oxford" Marmalade is made from an exclusive recipe which preserves the health-giving qualities of the finest Seville oranges. No colouring, flavouring matter or preservatives whatever are used.

Prolonged boiling and retention of the pip almost till the last stage of this process gives Frank Cooper's "Oxford" Marmalade that full piquant flavour. A healthy promoter of appetite—a tonic to the stomach and liver—Frank Cooper's "Oxford" Marmalade is a stimulating addition to the breakfast menu.

A one-pound jar of Frank Cooper's "Oxford" Marmalade will be sent free to any medical practitioner on request.

Coated Tongue and Toxemia

Coating on the tongue consists of epithelial cells, molds, yeast, and many bacteria, some highly virulent. Normally the saliva prevents growth of the latter. If the resistance of the blood is lowered, the saliva loses its germ-destroying and inhibiting power. A tongue coating appears.

In the constipated colon, putrefactive bacteria produce highly active poisons such as skatol, indol, etc. These enter the blood, lower its resistance, and thus weaken all fluid secretions such as the saliva. No wonder 85 per cent. of all sick people have coated tongues. Constipation is almost universal among the sick.

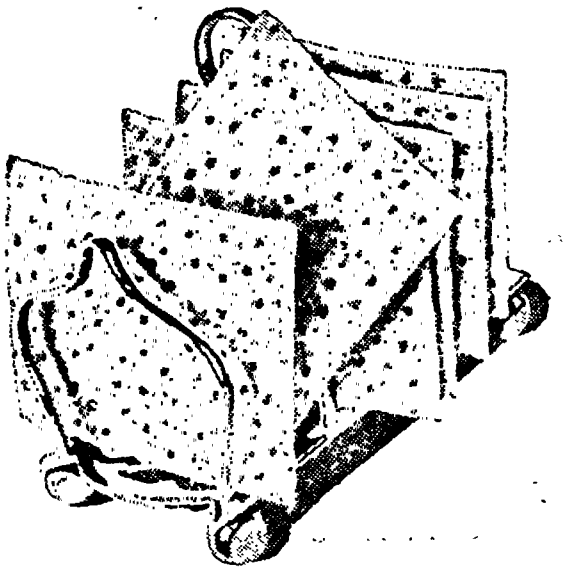
If the tongue indicates toxemia, prescribe Nujol—the safe and effective treatment. Many intestinal toxins are themselves absorbed by Nujol.

Nujol

REGISTERED TRADE MARK

Once absorbed by Nujol, intestinal toxins cannot be absorbed by the system, as Nujol itself is non-absorbable.

NUJOL DEPARTMENT, 128, Albert Street, Camden Town, London, N.W.1



Vita-Weat prescribed in place of ordinary bread

A most agreeable and beneficial alternative to soft wholemeal or white bread, especially in cases where a diet regime is prescribed, is to be found in Vita-Weat, the British whole wheat crispbread.

Vita-Weat presents the whole wheat berry in a *concentrated and digestible* form, with the Vitamins A, D and B in an active condition.

The *Practitioner*, reporting on Vita-Weat in August, 1927, said: "The value of this crispbread is not only in the vitamins it contains, but because it requires thorough mastication, while the branny scales serve *as a corrective to intestinal inertia.*"

The *Lancet*, in its report on June 11th, 1927, vouched for Vita-Weat in the following terms: "It will be noted that the caloric value is high." (The *Lancet's* own calculation was 1,846 per lb.) "It has a pleasant texture and flavour. . . . It is undoubtedly a valuable foodstuff, more particularly in respect of its content of Vitamin B."

The Royal Institute of Public Health report, printed in the *Journal of State Medicine*, Vol. XXXV, No. 8, stated that "Vita-Weat crispbread contains all the necessary elements and possesses a good physiological fuel value," and further said that the special method of manufacture "gelatinises the starch grains and thoroughly disintegrates the cellulose, fibre, etc., of the grains, *thereby rendering the finished product completely assimilable.*"

These valuable testimonials show that the regular use of Vita-Weat will promote health, vigour and physical fitness.

The confidence of the MEDICAL PROFESSION.

Benger's Food has gained its unique position not by extravagant or sensational advertising but by the constant recommendation of medical men and women. To-day it is universally used not only at home but throughout the world. Few foods have so enjoyed the approbation of the Medical Profession for over 40 years.

Benger's Food differs from all other foods in that it is especially prepared to adjust fresh cows' milk or cows' milk and water so as to suit the condition of any patient. While it is largely used as a routine treatment in all cases of disordered digestion the following comments, which have been recently made by Doctors, indicate some specific uses to which Benger's Food has been put.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."

"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."

"cancer of the stomach—doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."

"invariably used for invalids and aged persons."

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

Hypophosphites

An efficient Digestive, Tonic and Restorative

Invaluable in retarded convalescence and asthenic conditions generally

In 'Byno' Hypophosphites are combined the tonic qualities of the Nux Vomica and Cinchona alkaloids, the restorative value of the mineral hypophosphites, and the nutritive and digestive powers of 'Bynin' Liquid Malt which is the basis of the preparation.

'Byno' Hypophosphites has for long been prescribed with great success in convalescence after acute infections and following surgical operations; in nervous and mental conditions due to overstrain or exhaustion; as an adjunct in the treatment of tuberculosis; in asthenia of the aged and in a diversity of conditions where a general tonic and digestive is indicated.

In bottles at 3/6, 6/6 and 12/-

COMPOSITION:

Calcium Hypophosphite	2 gr.
Potassium	2 „
Sodium	2 „
Iron	½ „
Manganese	¼ „

COMPOSITION:

Cinchona Alkaloids ...	1½ gr.
Nux Vomica Alkaloids (equal to Strychnine)	1/10 „
'Bynin' Liquid Malt ...	1 oz.

THE "JACK SPRATT" CHILD.

"Jack Spratt could eat no fat"

Nervous children, the "Jack Spratts" of the nursery, digest fat badly. This fact has been emphasised recently by such eminent authorities as Still, Cameron & Osman.

Modern conditions of life make great demands on the nervous systems of such children. They are more highly strung, react more readily to emotional stimuli, and this strain is often reflected in digestive difficulties, such as cyclical vomiting, loss of appetite, constipation and bilious attacks.

It has been repeatedly demonstrated that these children cannot tolerate a diet rich in fat, and that whatever fats are to be dealt with must be metabolised in an excess of sugar. An insufficiency of sugar results in the production of ketone bodies and consequently ketosis. An excess of fat is split up in the bowels and neutralised by the valuable calcium and magnesium salts of the milk, which are subsequently excreted in the familiar pale, dry, and crumbling stools.

To meet the needs of this type of infant the manufacturers of "Cow & Gate" Milk Foods have provided a

HALF CREAM

PACKED IN A BLUE TIN

Cow & Gate Milk Food

PACKED IN A BLUE TIN

This food has the following composition:—

	Dry Food	Reconstituted (1 part in 8 parts of water)
Fat	15.5	1.7
Proteins	20.0	2.2
Lactose	58.0	6.4
Mineral Matter	4.5	0.5

Half Cream "Cow & Gate" has been used in the large class of "nervous dyspepsias" of infancy with eminently satisfactory results, proving invaluable as a food during periods of fat intolerance so noticeable in the "Jack Spratt" type of infant.

The manufacturers will gladly supply samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

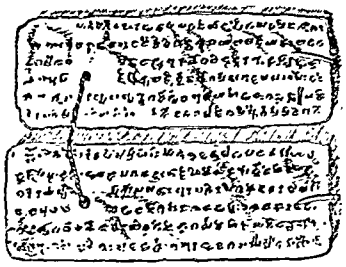
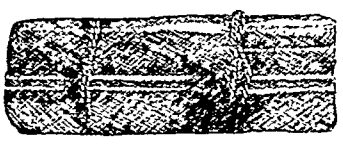
AN ANCIENT INDIAN MANUSCRIPT-BOOK—OPEN and CLOSED.





These illustrations show the external form given to their productions by the pioneer makers of books in India. The palm-leaf, the earliest "paper" used by them, appears to have determined the narrow, elongated *format*, for which birch-bark, and, much later, paper came to be employed, these materials being cut to the shape of the original palm-leaf pages. Palm leaves are still used for writing material in parts of India. The *pothi* (from Sanskrit *pustikā*, book), as here illustrated, consisted of a number of pages of palm-leaf, or of birch-bark cut into uniform strips in imitation of palm-leaf pages, enclosed between two wooden boards and "bound" by a string which passed through holes bored in all the pages, and tied when the volume was closed.

BELLE VUE SPA

TEFRIW, NORTH WALES.

(Railway Station: Llanrwst and Tefriw.)

ARTHRITIS.
AMBULATORY TREATMENT.

Mobility and freedom from pain in crippling arthritis of the hip and knee even after shortening and contracture have occurred.

This is the special achievement of BELLE VUE SPA; secured by Hoefftcke's extension appliances, which maintain continuous extension by night and by day.

The appliance permits the patient to walk, and not only takes the body weight but replaces the normal state of compression of the leg by one of active stretching.

There is no other satisfactory way of combining movement with extension.

The method secures:

1. Extension without muscle loss inevitable when the patient is kept in bed.
2. Extension without the vascular stasis which occurs when a joint is kept at rest,

AND

MOVEMENT WITHOUT PAIN.

The result is rapid reconstruction of the joint with astounding restoration of function in those advanced cases which have hitherto seemed hopeless and incurable.

BELLE VUE SPA is well equipped for auxiliary treatment by massage, electricity, diet, light, etc., and full advantage is taken of the tonic virtues of its chalybeate waters.

An Address
ON
PELVIC SEPSIS.

GIVEN TO THE SOUTH-WEST ESSEX DIVISION OF THE BRITISH MEDICAL ASSOCIATION

BY

A. LOUISE McILROY, D.B.E., M.D., D.Sc.GLAS.,
PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, UNIVERSITY OF LONDON (ROYAL FREE HOSPITAL).

PELVIC SEPSIS is one of the most important subjects in medicine. It is a danger to life. It is the cause of ill health on the part of many women. It interferes with reproductive function, and leads to more domestic anxiety and conjugal infelicity than almost any other disease.

What are the natural defences of the pelvic organs against infection? Although the reproductive organs consist of a series of canals which potentially lead from the open air to the peritoneal cavity, the structure of these passages is so arranged as to ensure almost complete occlusion. The labia close over the vaginal entrance, and the walls of the latter lie in antero-posterior apposition. The cervical canal is narrow and sealed by mucus. The secretion of the uterine glands, the cilia, the muscular contractions, all prevent the ascent of bacteria. The tortuous condition of the Fallopian tube is an important element in the closure of its lumen. The vagina contains the bacillus of Döderlein, which is a powerful agent against the entrance of infection. When this bacillus is present pathological bacteria are as a rule absent. Dr. Charlotte Houlton, in the Obstetrical Unit at the Royal Free Hospital, made a very comprehensive investigation of the vaginal and cervical discharge during pregnancy. If the *Bacillus vaginalis* was present in numbers puerperal sepsis was less likely to occur than in those cases where the bacilli were scanty or absent. Various other research workers have also found that streptococci are so frequently present in the vagina as to warrant the assumption that these bacteria are protective in function.

With all these methods of defence, how does infection gain an entrance? Mainly by means of the exercise of the reproductive function. In virgins pelvic sepsis is rare, apart from toxic intestinal conditions or tuberculous lesions. The mode of invasion is mainly by the pelvic route by direct infection, as in gonorrhoea, or from infection occurring at the time of labour or abortion. The most important organisms we have to deal with are the gonococcus, the streptococcus, and the *Bacillus coli*. The gonococcus is rarely to be found except in the acute stage, and I do not propose to deal with the subject of venereal disease except to mention that in cases of chronic pelvic sepsis in hospital practice which do not yield to treatment the gonococcus is the chief factor for consideration. Sepsis may gain admission by means of the blood and lymphatics. Septic foci, such as are found in carious teeth or intestinal toxaemia, are a source of infection. The *Bacillus coli* may affect the urinary tract and give rise to pelvic complications. Streptococci or *B. coli* infection of the caecum or appendix may involve the right tube and ovary. The vulva and vagina are not easily infected apart from venereal disease. The cervix may retain bacteria because of its crypts and complicated glands, and a chronic discharge may persist for months or years. Recurrent vascular changes in the endometrium and the formation and exfoliation of the decidua render the uterus liable to attacks of micro-organisms.

Infection during Pregnancy.

In pregnancy infection is not common. The most common infection is by the *Bacillus coli*. It is closely associated with toxaemia and pre-eclamptic manifestations. Urinary symptoms should never be ignored in pregnancy, and bacteriological examinations of the urine should be carried out if toxaemia is present. The presence of albumin is not the only important factor in urinary analysis. Treatment of *B. coli* infection by the oral administration of alkalis, followed by acids and formalin preparations, is much to be preferred to local applications and douches to the bladder. The treatment of urinary infections in pregnancy is, as a rule, satisfactory. Rest in bed, heat to the abdomen, fluid diet, and non-protein solids, with plenty of fresh fruit and vegetables, give good results. Pregnancy rarely has to be terminated for *B. coli* infection, and only in those cases where there is kidney involvement. The bacilli may persist in the urine for weeks after the patient appears cured. No special clinical significance seems to be attached to their presence in such cases.

General ill health in pregnancy means low resistance to infection at the time of labour. The teeth should be examined as a routine, and attended to when caries or pyorrhoea is present. Even one carious tooth can affect the well-being of a patient. About 70 per cent. of the ordinary hospital patients attending the ante-natal clinics require dental treatment, even though it may merely mean cleaning the teeth and gums. I have never seen abortion occur as the result of dental extraction. On the contrary, many cases of habitual abortion owe the condition to septic mouths. Every focus of infection, such as in disease of the middle ear or skin, should be treated. Defective states of the excretory organs, especially intestinal stasis, and abnormal conditions of the heart and lungs all lower resistance to infection.

If there is a purulent discharge from the cervix a swab should be taken for bacteriological examination. Vaginal swabs are useless. Treatment by antiseptic swabbing of the cervix or by medicated pessaries can be given. Lactic acid pessaries are of benefit, as they stimulate the growth of the vaginal bacillus. Douching is of no value unless carried out by a nurse. It often does more harm than good if left to the patient herself. It inhibits the protective bacteria, and should only be employed for infective discharges. It is quite unnecessary to douche patients during labour or before the application of forceps. A not uncommon cause of puerperal infection is intercourse in the later weeks of pregnancy.

Labour.

Sepsis may be introduced directly by the attendant by means of repeated vaginal examinations, but in the majority of cases the infection is in the patient herself. Lacerated and especially contused tissues may become infected in any part of the body, and the same condition may occur in the pelvic organs. Bacteria which are harmless on an intact mucous surface may easily take on a pathological character when they gain access to tissues filled with blood and damaged cells. Saprophytic organisms invade blood clot or placental tissue which is separated or necrosed, and in some cases they prepare the way for the invasion of pyogenic bacteria. Lacerations are not so likely to occur if the labour is easy and not unduly hurried. An easy labour means less shock, and therefore less lowering of resistance. If the patient is assured that she will not suffer the results are better.

The psychological aspect of labour is of great importance. Fear is often inhibitory in its influence, and causes contraction of the outlet of the pelvis. Shock can be avoided to a great extent by the administration of sedatives in the first stage, sedatives and intermittent anaesthetics in the second stage, and full anaesthesia in primigravidae when delivery is taking place. In domestic practice the medical attendant may be forced to interfere with the course of labour against his better judgement because of the suffering of the patient or the persuasions of her anxious relatives. If the patient sleeps or does not complain of pain the conduct of the labour is much more easy. Chloral hydrate and potassium bromide can be given with safety from the beginning of painful labour and throughout. Morphine is the most efficacious of all drugs, as it hastens the dilatation of the cervix; opoidine, 1/6 to 1/4 grain, is a good preparation of morphine to be given in the first stage. Adaline, 5 to 10 grains, is also useful, and easily administered by the mouth. There is no rule for the repetition of the dose in labour; the dose is regulated by the condition of the patient. The best anaesthetic is gas and oxygen, but it is cumbersome for domestic practice. Chloroform is useful during delivery and at intervals during the later second stage. If the patient is anaesthetized so as to

prevent undue pressure during the delivery of the head, damage to the perineum can be prevented in many cases. In obstetric practice it is not always possible to have an anaesthetist, because of the additional expense. No surgeon would operate under the conditions enforced upon a practitioner in maternity work. Lacerations of the cervix should always be looked for by means of a speculum, and if present stitches must be applied. Tears in the vagina require repair just as much as the perineum. How is this all to be carried out if the light is bad and the patient rolling about the bed? If midwifery practice is to be improved the public must be made to realize that it means more financial responsibility. Skilled medical help in the repair of lacerated tissues will solve to some extent the problem of maternal mortality. Although ante-natal work is doing much to prevent complications in labour, we must direct more attention in the future to the more rational treatment of labour itself and its immediate consequences. If over 60 per cent. of the women of the country are attended by midwives, are these labours to be borne with pain and suffering? Every expectant mother should be seen at least once by a medical practitioner, and I see no reason why he should not arrange for a suitable sedative to be given by the midwife during labour in each particular case. If there is great suffering and an anaesthetic would give relief, this should be an indication for sending for a practitioner, preferably one who has already seen the patient during pregnancy. Pupil midwives should be given some special training in the administration of sedatives. Drugs such as chloral hydrate and potassium bromide could be put up in measured doses and indications taught for their safe administration. Anaesthetics should be given by the medical practitioner as in surgical practice. The obstetric attendant cannot be expected to deliver or operate and give an anaesthetic at the same time. I am not quite sure of the legal aspect of the case, but I could quite well imagine some difficulty arising in the case of a fatal termination from anaesthesia if only one medical practitioner were present.

The practice of making women bear down in labour often results in general and uterine fatigue. Pressing the feet against a board is less tiring than pulling with the arms. Sometimes the squatting position aids the descent of the head.

Third Stage of Labour.

As long as the placenta is in the uterus and no haemorrhage is taking place the uterus should not be manipulated, as irregular contractions may be retracted upwards towards the placenta is adherent and manual removal is necessary, edge of the membranes may be retracted upwards towards the cervix, thus causing infection. When the placenta reaches the vagina it can be expelled by gentle massage. If it is not infrequently found that a certain degree of sepsis follows. In cows, if the placenta is adherent, *B. coli* infection is suspected. It may be that a parallel condition exists in human obstetric practice, and that the infection is already in the uterus. To remove an adherent placenta it is better to keep the hand inside the uterus when the placenta is entirely separated and to pull it out by the cord with the other hand. If it is not intact or membranes are left behind, the internal hand can clear the uterus without additional risk of reintroduction. Exploration is unnecessary for retained membranes or small pieces of placenta in other cases, because of the risk of introducing sepsis. The patient should be carefully watched, and if signs of sepsis appear the uterus can be drained or explored. As a rule the uterus expels all retained membranes, and can be aided to do so by the administration of fermogen or pituitrin.

Drainage of the uterus in the puerperium may be aided by sitting up in bed and by exercises. Lochia are retained if the patient lies on her back for any length of time. If the perineum has been lacerated and healing does not take place the stitches should be removed and the perineum cleaned up with antiseptics and sitz baths. As soon as tissue are clean usually in about ten days—the patient should be anaesthetized and deep silkworm-gut secondary sutures applied after freshening the granulation tissue with a scalpel. If the perineum is slow in becoming clean [illegible] applied for a few days stimulates the [illegible] underlying tissues and renders operation possible. Complete union as a rule occurs after suturing, and thus vaginal operations for prolapse are prevented. This method of treatment is most satisfactory, and is carried out as a routine in the Obstetrical Unit in every case where healing has not taken place.

Local Sepsis: Diagnosis and Treatment.

True puerperal sepsis, or septicaemia with blood infection, is not common in hospital obstetric practice, but local sepsis is met with not infrequently. District patients rarely go septic, probably because of their protective organisms. These may be destroyed when a patient comes into hospital, in the process of cleansing.

Local sepsis, in addition to a rise of temperature and pulse, is manifested usually by offensive-smelling intermittent copious lochial discharge. The uterus is tender, and the abdomen is not distended. The main object of treatment is to stimulate uterine drainage and contractions. Ergot, pituitrin, or quinine can be given. Low-pressure vaginal douches are of benefit, also sitz baths. Drainage by means of a wick of gauze with glycerin in the uterine cavity is effective. In some cases digital exploration is necessary to remove pieces of placenta. If pus forms incisions must be made, but with early glycerin drainage cases of pelvic cellulitis have almost completely disappeared. A fresh wick of glycerin gauze is put in daily until the temperature subsides. This method is easier of application than the frequent injections of glycerin as recommended by Dr. Remington Hobbs. As a rule two, or at the most three, applications are sufficient.

Treatment of Acute Sepsis.

In acute sepsis rigors are present in many cases, the lochia dry up, and the abdomen is tender and distended by the paralysed intestine. Streptococci may be found in the blood, usually when the temperature is high. Sometimes the *Bacillus coli* is found, but not frequently. The treatment is more general than local. Antistreptococcus serum in daily doses of 20 to 30 c.cm., or even 40 c.cm., is given. Quinine bihydrochloride intramuscularly, 5 to 10 grains daily, is also given. The two essentials, however, are open air and daily colon lavage. The latter clears away the intestinal toxins, and is the most efficient remedy I know of for sepsis. It helps to prevent the onset of pneumonia. Blood transfusion is of value in some cases. If there is any uterine discharge a glycerin drain may be employed. Vaccines, unless in stock, are difficult to obtain in time for immediate treatment. The Dick serum has not proved itself of much benefit according to the researches of Dr. Salmond and Dr. Turner in the Obstetric Unit at the Royal Free Hospital.

Post-natal care is essential in the prevention of the extension of latent sepsis. The uterus should be encouraged to rise up in the pelvis by making the patient take knee-chest exercises. A pessary may be necessary for a month or two if the uterus is not involuted. If catarrhal conditions of the cervix are present vaginal tampons of ichthyol and glycerin are of use. Operative treatment should not be advised until all other methods of treatment have proved useless and symptoms are present and found to be definitely due to the malpresentation.

Abortion is a very frequent cause of pelvic sepsis, especially if criminal induction has taken place. Drug induction often causes an incomplete abortion, with consequent chronic ill health. As a rule the placenta is retained, and may become foul-smelling with septic necrosis. The patient should be treated as a case of acute sepsis and her resistance raised. Glycerin should be injected into the uterus, and after the acute symptoms have subsided the placenta can be removed by the fingers or ovum forceps. Early removal of the placenta may break down the protective cell barrier in the uterine wall and so turn a local into a general sepsis. Curettage or hysterectomy for puerperal sepsis have been given up by most obstetricians.

Pelvic Sepsis in Gynaecological Practice.

I cannot do more than touch upon one or two points on this subject. Most infections are puerperal or gonorrhoeal in origin. In the treatment of chronic pelvic sepsis the

medical aspect of the question is coming more into prominence than hitherto. The general condition of the patient is more important than the local. Chronic cervical discharge may clear up in many cases with local treatment, but the uterus is frequently the channel for the excretion of toxic products, the result of intestinal stasis or rheumatic affections. Teeth are a source of chronic infection. Dieting, exercise, baths, intestinal lavage, and artificial sunlight all help towards a cure. If there is stenosis of the cervical canal or retained uterine discharge, as in cases of chronic subinvolution with defective uterine contractions, local treatment, such as dilatation, curettage, and drainage, is valuable. Drainage can be carried out by stitching a self-retaining rubber catheter into the uterus for five or six days and injecting a drachm of glycerin with a serum syringe into the tube several times a day. This does not disturb the patient, and can be done by a nurse. Glycerin drainage relieves the pain and uterine spasm of acute sepsis, such as occurs in salpingitis or pyosalpinx. It is used as a preliminary measure to operation, but in many cases of pelvic peritonitis the symptoms subside with drainage, and operative intervention is unnecessary. It is useless operating upon adherent tubes and ovaries if the uterine canal is stenosed. A preliminary dilatation and drainage is necessary. If pus is present in the tubes, and removal or some conservative operation is adopted, drainage of the pelvis is best performed by placing a wick of gauze in the pouch of Douglas and bringing one end out through a vaginal incision. Amputation of the cervix for chronic sepsis may give good results if pregnancy does not occur subsequently, but rigidity from scar tissue may complicate labour. I have seen several cases where Cæsarean section was necessary for this condition. The operation is not a desirable one in the case of young women. Hysterectomy for chronic sepsis is beneficial when drainage has failed, but it is not so frequently employed now that general methods of treatment are available.

The restoration of reproductive function, and not its destruction, should be the aim of the practitioner. A radical pelvic operation should not be performed before treatment of septic teeth or intestinal stasis has been tried. Hysterectomy, if performed, should, when possible, be limited to the supravaginal operation. Panhysterectomy causes contraction of the vaginal vault, with subsequent dyspareunia or difficult intercourse. Hysterectomy not only causes sterility, but gives rise in some cases to domestic unhappiness and infidelity, both on account of its physical and mental consequences. The after-histories of cases when followed up may make one question the advisability of radical operations, which may physically benefit the patient but cause unhappiness in her marital relationships. If the uterus is removed and the ovaries are left, the cervix acts to a certain extent as a channel of excretion.

Tuberculous affections of the pelvic organs should be treated on the same lines as surgical tuberculosis—fresh air and sunlight. The recurrence of menstruation may cause attacks of pain and keep up the activity of the disease. X rays are of value in suppressing menstruation and thus bringing about physiological rest. The dose can be graded to be temporary in its effects.

I have merely touched upon the fringe of the subject of pelvic sepsis. My opinions are perhaps controversial, but they are at least the result of my experience.

"ACTIVATED" (IRRADIATED) FLUORESCEIN IN THE TREATMENT OF CANCER.

BY

S. MONCKTON COPEMAN, M.D., F.R.C.P., F.R.S.,
FRANK COKE, F.R.C.S.,
AND
CLAUDE GOULDESBROUGH, M.B., B.Ch.,
RADIOLOGIST TO THE ROYAL NORTHERN HOSPITAL.

(*With Special Plate.*)

Two years ago (in 1927) we tentatively initiated a method of treatment on cases of inoperable cancer involving the use of a soluble salt of fluorescein, followed by the application of a comparatively small dosage of *x* rays or radium.

This method, and the results obtained therefrom, formed the subject of preliminary communications by one of us (S. M. C.) to a meeting of the local Branch of the British Medical Association at the Hampstead General Hospital on February 9th, 1928, and to the Chemio-Therapeutic Section of the International Cancer Conference[1] which met in London in July of that year. On the occasion of the London conference we also demonstrated at the Royal Northern Hospital several cases of previously inoperable cancer, which, subsequent to varying periods of treatment, then exhibited no evidences of the malignant disease from which they were suffering when treatment by means of activated fluorescein was commenced.

Activation of Fluorescein.

Fluorescein ($C_{20}H_{12}O_5$), which may be regarded as the prototype of a long serious of acid phthalein dye-stuffs, is formed by heating to a temperature of 190° C. a mixture of phthalic anhydride (1 part) and resorcinol (2 parts). By the introduction of halogen atoms into its molecule most of the fluorescein produced is transformed into dye-stuffs known by the generic term of "eosins." Of these the most important is eosin ($C_{20}H_6O_5Br_4K_2$), well known by reason of its extensive use in histological investigations. This is the potassium salt of tetra-brom-fluorescein, which is usually marketed rather than the sodium salt, which does not crystallize so well. On the other hand, fluorescein, which is quite insoluble in water, but readily soluble in alkaline liquids, is produced as the sodium salt, under the trade name of uranin. In the course of our investigations we have also made use of the potassium salt, but found it necessary to have this specially prepared.

For some years past it has been known, as the outcome of researches by von Tappeiner and Raab, Noguchi, Salant and Bengis, Pereira, and others, that when lowly organisms such as paramoecia, or embryonic cells, including ova and spermatazoa, are exposed to the action of daylight in the presence of a dilute solution of eosin or fluorescein they are rapidly killed, whereas if protected from light, as when the containing vessel is placed in a dark cupboard, no such lethal effect is produced. Many other dyes, dye-stuffs, and acridine derivatives, in addition to haematoporphyrin, a derivative of haemoglobin, all of which fluoresce in the presence of light, exhibit similar properties. This fact has been abundantly demonstrated in the case of eosin, most recently by Pereira.

Eosin, and the similar iodine compound erythrosin, have, however, from the clinical point of view, the disadvantage as compared with fluorescein, that, especially if injected intravenously, they are found to be definitely toxic to the animal body, whereas fluorescein appears to be completely non-toxic even if administered in comparatively enormous doses. Thus experiments carried out by W. S. C. Copeman and D. Levi have proved that continuous administration of 1 per cent. fluorescein to mice, over a period of several weeks, in place of water, has no obvious harmful effect; while tadpoles can live in a 1 per cent. solution of fluorescein, if protected from light, for a shorter period of time.

Dr. H. Colwell, radiologist to King's College Hospital, is at present engaged in an investigation on somewhat similar lines with the aid of a grant from the Medical Research Council, but his report has not yet become available.

Recently, in view of suggestions received from Professor Lindemann, F.R.S., of Oxford, we have carried out a series of tests, clinical and experimental, on the action of fluorescein salts of metals other than sodium with, and

department of the Royal Northern Hospital. The tabulated list of cases kindly supplied by the secretary of the hospital affords, on analysis, the following results:

Apparent recovery	8
Much improved	20
Too recent for statement	7
No change	8
Not improved	2
Discontinued treatment	12
Dead	7
Prophylactic	6
	70

As regards patients treated elsewhere, four successful cases have been reported to us from King's College Hospital; two cases of carcinoma of the breast in private practice have apparently recovered; and several instances have come to our knowledge in which recurrent nodules on or near operation scars have disappeared. In a letter recently received from Drs. Dight and Cutter of Sydney, Australia, the writers say, *inter alia*: "We have tried the method in a number of cases . . . and, so far, our results are very encouraging." They give certain details as to a case of "obstructive neoplasm of the œsophagus," treated by means of intravenous injections of 10 c.cm. of a 1 per cent. solution of potassium fluorescein in normal saline before each irradiation given at intervals of fourteen days, with the result that "whereas before the treatment the patient had difficulty in swallowing fluids, she now can take semi-solids quite easily."

Recently a test was carried out on similar lines to those adopted in our first case, radium, however, being employed in place of *x* rays.

The patient was a man, aged 39, who had been operated on at varying intervals on five separate occasions for sarcoma of the thigh. Recurrence having taken place in the form of a fungating mass measuring about 4 by 3 inches and raised above the surface of the surrounding skin, it was decided to treat it with radium, the inner half of the growth being also painted and injected with 2.5 per cent. Na-fluorescein solution. Radium was used in the form of radon, a number of tubes containing which were inserted around the periphery of the growth. Some weeks later letters were received from Mr. Clifford Morson, the surgeon in charge, and from Dr. Muir, medical superintendent of Whipp's Cross Hospital, stating, in each instance, that the effect produced was definitely more marked on the portion of the tumour treated with radium + fluorescein.

To Mr. Stanford Cade of Westminster Hospital we are indebted for the following notes of two of his cases, which also afford evidence that the simultaneous use of fluorescein may considerably augment the action of radium.

Case 1.—Mrs. A. S., aged 55. Atrophic schirrosis of right breast; fourteen years' history. Ulceration and tumour. Treated by me with radium application, and daily painting with fluorescein while the radium was in position. Complete disappearance of the lesions, although the total quantity of radium was much smaller than what I use as a rule.

Case 2.—Mrs. T. B., aged 50. Carcinoma of breast, secondary deposits above clavicle and in axilla. Same treatment as in previous case. Complete disap[illegible] ummary tumour and axillary glands; marke[illegible] raclavicular glands. In this case, too, in my [illegible] has accelerated the reactions to irradiation.

Dr. Mottram,[2] experimenting with the cells of rat sarcoma with which other rats were subsequently inoculated, has shown that dosages of radium and of fluorescein, each incapable alone of exerting any appreciable restraining effect on the growth of the cell substance inoculated, nevertheless, in conjunction, though apparently irrespective of which is first applied, exhibit such summated action as to prevent growth of tumours in the majority of the subsequently inoculated animals.

The fact that it is possible so greatly to augment the action of radium by the concurrent use of fluorescein is obviously of considerable interest, and likely to prove of practical importance where perhaps only a minimal amount of radium is available for purposes of treatment.

Finally we desire to direct attention to a few points which we have found to exert a definite influence on the extent of success likely to be attained by the use of "activated" fluorescein in the treatment of certain forms of cancer.

(*a*) Cases which respond most satisfactorily are those in which other methods of treatment have not previously been employed. If the patient has already been subjected to courses of *x* rays or radium, this fact will probably militate against obtaining useful results with fluorescein.

(*b*) The more cellular and rapidly growing (that is, the more malignant) the growth, the more readily is it likely to respond to treatment.

(*c*) When fluorescein is given internally, in the course of treatment of cases of breast cancer, enlarged glands in the axilla have been found to disappear although not themselves directly activated.

(*d*) In the case of superficial secondary growths, such as recurrent nodules on or near the scar of an operation wound, excellent results have been obtained by the injection with a hypodermic needle of a few drops of fluorescein solution into the substance of the nodule prior to irradiation. Treated in this way, secondary nodules even of considerable size may disappear with unexpected rapidity.

(*e*) Cases previously regarded as inoperable, after a course of treatment with activated fluorescein have, in certain instances, been found, at a comparatively early stage, to have undergone such changes as to render them amenable to surgical intervention with satisfactory results.

LESIONS OF LATENT SYPHILIS.*

BY

ALDRED SCOTT WARTHIN, PH.D., M.D., LL.D., M.A.C.P.,

PROFESSOR OF PATHOLOGY, AND DIRECTOR OF THE PATHOLOGICAL LABORATORIES IN THE UNIVERSITY OF MICHIGAN, ANN ARBOR.

(*With Special Plate.*)

SINCE 1906 I have made an intensive study of the histologic lesions of latent syphilis in relationship to the presence in these lesions of the etiologic agent of syphilis, the *Spirochæta pallida*. The results of this work have been published from time to time in various articles in American medical journals. This study began with the demonstration of spirochaetes in the myocardium and with the establishment of the histologic entity of syphilitic myocarditis. The first studies were made with the Levaditi method; because of the length of time required for it and because of the large number of negative results obtained by this method from cases showing identical histologic lesions as those seen in positive cases, my attention was drawn to the necessity of developing a better staining method than the Levaditi. With the aid of my assistant Dr. Starry, there was perfected the Warthin-Starry silver-agar method, which possessed great advantages over the Levaditi method, notably in the reduction of time required, from ten days to ten hours or less, in the use of the method on single sections mounted on cover-glasses, thereby permitting a control of the histologic lesions, and finally in the much greater percentage of positive spirochaete finding. Through the use of this staining method the greater part of my work on latent syphilis has been carried out, but the method, although in our opinion much superior to the Levaditi method in every way, is still far from being a perfect method, in that it does not give more than 60 to 75 per cent. of positive spirochaete demonstrations in cases showing identical tissue lesions. This has led us to continuous experimentation with staining methods, and recently in my laboratory we have developed a silver-starch modification of the Warthin-Starry method which promises a higher percentage of positive results than with the old method.

The material upon which this study has been carried out has been chiefly necropsy material coming into my laboratory from the University Hospital clinics. As this hospital is a State institution, its patients are drawn from all over the State of Michigan, largely from the small towns and rural districts. It represents chiefly the lower middle-class population. The present necropsy service examines about

* A paper read in opening a discussion in the Section of Venereal Diseases at the Annual Meeting of the British Medical Association, Manchester, 1929.

300 to 350 cases a year. A systematic microscopic study of all organs and tissues from each necropsy is made, and cases showing histologic lesions of syphilis are then checked with the spirochaete stain. The percentage of syphilis in this post-mortem material is very high, but shows a great variation in different years—30 to 60 per cent. A very large percentage of these cases are middle-aged males, who have entered the hospital because of cardio-vascular symptoms, or who have died from heart failure while in the hospital for surgical operations. A smaller number have been known cases of syphilis with history of treatment. Based upon the study of this material, I have arrived at the following conclusions regarding the occurrence of latent syphilis in the various organs and tissues of the body.

Leptomeninges.

Lesions of latent syphilis occur very frequently in the meninges, being present in the great majority of cases. They vary greatly in intensity, from small, localized opacities or thickenings to more patchy or even generalized thickenings of the arachnoid and pia. They are found most frequently over the parietal and frontal lobes, usually over the sulci, and not over the convolutions. In the active latent lesions these meningeal thickenings and opacities appear microscopically as localized areas of a mild productive process with slight infiltrations of monocytes, plasma cells, and lymphoid cells. There is a proliferation and increase of the reticulo-endothelial cells of the membranes, with eventually cells of fibroblastic type leading to fibrosis. Small perivascular collections of lymphocytes and plasma cells may occur throughout the meninges; the number and degree of these being in proportion to the severity of the process. In many cases there is only a slight productive reaction, leading slowly to thickening and hyaline change in the membranes. The sharply localized character of these mild lesions is very striking. Often they are seen in the gross with difficulty, by oblique light or upon floating the membrane. In the old case of latent syphilis the process may be for the greater part healed or inactive; the membranes show hyaline thickening, while cellular areas may be found only after prolonged search. Every transition stage of severity may occur, from slight fibrosis of the meninges to the active and clinically recognizable form of syphilitic meningitis.

Brain.

Localized perivascular infiltrations occur within the brain tissue of the latent syphilitic. They are precisely similar to those found in paresis and cerebral syphilis, the difference being only in number and degree. They occur usually throughout the frontal and parietal lobes, and near the ventricles. They are usually few in number; in some brains only one or two such infiltrations may be found on extensive examination microscopically. Here again all transition stages in degree and number of these lesions occur, up to active brain syphilis and paresis. In many cases of syphilitic psychoses these latent lesions are found in very moderate numbers associated with a moderate atrophy and gliosis of the brain tissue, involving particularly the frontal lobes. It may be said that every latent syphilitic has localized lesions identical with those of paresis, the only difference being in the number and intensity of these lesions. The meningeal lesions and those of the brain tissue do not always show a corresponding degree of involvement; as a rule the meningeal lesions are more numerous and more marked than the cerebral.

Spinal Cord.

Similar lesions are found in the meninges of the cord and in the cord itself, but less frequently than in the brain.

Heart.

In my experience the heart of every male latent syphilitic has shown latent lesions, varying from small and few microscopic areas of increased stroma nuclei and plasma cell and lymphocyte infiltrations up to more diffuse areas of interstitial myocarditis. In the majority of latent syphilitic females these cardiac lesions do not occur, or are very small. Nevertheless, in some women more severe forms of syphilitic myocarditis do occur. The part of the heart usually involved in these latent lesions is the septum, and the anterior and posterior walls of the left ventricle near the apex, rather than the walls of the right ventricle, although in some cases the right ventricle has shown more marked involvement than the left. The lesions are usually intermuscular, rather than perivascular. In the mildest degree they consist of an increase in the number of stroma nuclei, the latter being arranged in single or double file, occasionally with large aggregations of nuclei between the muscle. These aggregations represent perivascular infiltrations around the smallest coronary branches. The infiltrations present a variety of cell forms: plasma cells, lymphocytes, monocytes, and cells of fibroblastic type. Occasionally polynuclears are present. The chief characteristic of these infiltrations is their diffuse or patchy character. They are not sharply demarcated, but trail off irregularly into the neighbouring heart muscle. The papillary muscles are often involved. Very characteristic is an increase of nuclei beneath the endocardium, the cells lying in two to five rows, closely crowded together. They appear to be derivatives chiefly of the subendothelial reticulo-endothelial cells. The stroma often appears markedly oedematous, as in congenital cardiac syphilis, and very frequently it gives a mucoid reaction with mucin-staining dyes. The more active the process, the more marked is the oedema. Fibrosis of the myocardium is the eventual result of this interstitial proliferation and infiltration. Between the active infiltrations the heart muscle fibres are well preserved, often hypertrophic. As the active cellular infiltration diminishes and fibrosis results, the heart muscle becomes atrophic, and often shows fatty degenerative infiltration. In many cases the fibrosis of the stroma takes place without much change in the muscle fibres. Ultimately, however, atrophy of the muscle results, and there is a patchy fibrosis of the myocardium containing atrophic fibres. This latter distinguishes infarct scars from the syphilitic fibrosis; the former being more sharply circumscribed and devoid of muscle fibres in their central portions, at least. Spirochaetes may be found, often after prolonged search, in the active infiltrations, and even in the scar tissue, when the latter is still fairly cellular. When the fibrosis becomes hyaline it is impossible to find them. Hence the advantage of the Warthin-Starry method of staining spirochaetes in single sections, permitting control of the histologic lesions. With the exception of the aortic, the valves are rarely involved in latent syphilis. The aortic valves are affected chiefly through the vasa vasorum of the aorta, and a certain degree of sclerosis of the aortic valves is almost always present in the latent syphilitic in later years. Acute exacerbations of the latent lesions occur without known cause, and are characterized by a polymorphonuclear infiltration, in which spirochaetes are present.

The heart of the latent syphilitic usually shows at necropsy dilatation of the left ventricle or of both ventricles. In the great majority of cases there is no valvular lesion, although the sequelae of bacterial endocarditis may be coincident in some cases. In the younger individual latent syphilis of the heart probably predisposes to secondary bacterial endocarditis, as numerous cases showing this combination have been observed. In the older cases the majority show no secondary valvular involvement. The great majority of cases of latent syphilis come into the clinic of internal medicine as patients showing more or less vague myocardial insufficiency, with symptoms of dyspnoea, palpitation, slight or marked cyanosis, and chronic passive congestion. They represent a definite cardio-vascular complex. When questioned as to the occurrence of rheumatic symptoms they almost invariably give affirmative answers, and the common clinical diagnosis is therefore "rheumatic heart," even in the absence of all evidence of valvular lesion. A progressive course downhill of increasing cardiac dilatation and insufficiency follows, and the cause of death in the latent syphilitic is most frequently "cardiac or myocardial insufficiency." To what extent this cardiac failure is due to the myocardial lesion or to the associated aortic lesions is usually very difficult to determine. At necropsy the heart is dilated, the wall thin and atrophic, with a certain degree of subendocardial fatty degenerative infiltration. The endocardium is usually

more or less thickened and opaque. Cross-section of the heart wall will show more or less marked irregular areas of fibrosis, particularly in the left ventricular wall towards the apex. A cardiac death is a very frequent form of death for the latent male syphilitic, and a large percentage of the deaths occurring in middle life from "myocardial degeneration" are due to this cause.

Aorta.

Latent active lesions are found in the aorta of every male syphilitic and in the majority of female syphilitics, although usually they are much less marked in the women than in the men. The lesion is essentially a disease of the vasa vasorum, consisting in obliteration and thickening of the walls of the small nutrient arterioles of the aorta, with plasma cell and lymphocyte infiltrations along the course of these vessels. The term "mesaortitis" is a misnomer, as syphilis of the aorta does not affect primarily the muscle coat of the vessel, but is primarily localized in the vasa vasorum. The infiltrations are always more marked in the adventitia around the larger vasa vasorum than in the media, decreasing in size towards the intima. As the result of the obliteration of the nutrient vessels there is a slow infarction of the intima and inner portion of the media, resulting in sclerosis and atrophy of the muscle and degeneration of the yellow elastic tissue. In the mildest cases small infiltrations are found only in the adventitia and around the para-aortic blood vessels. The gross pathological picture in the mild cases of aortic syphilis is that of a single area of aortic sclerosis or atherosclerosis. In many cases it cannot be diagnosed as syphilitic in character from the gross appearances. Even in aortas that appear normal latent syphilitic lesions can be found in the adventitia around the vasa vasorum. The gross appearance of any aorta cannot be taken as a criterion for the absence of active syphilitic lesions in its wall; only the microscopic examination can decide as to the absence or presence of syphilis. It is in the severe forms of aortic syphilis that characteristic lesions of syphilis show grossly in the form of irregular fissures and depressions in the intima with the characteristic porcelain-blue appearance. In the great majority of cases, however, the changes produced in the aortic wall by syphilis are covered up by the associated secondary sclerosis of intima and inner portion of the media.

Syphilis of the aorta may exist in three forms: with aneurysm; with aortic insufficiency; and in the form of perivascular lesions around the vasa vasorum in the absence of both aneurysm and aortic insufficiency. The third form is by far the most common, but is rarely recognized by the clinician. It may be either symptomless, or present the clinical syndrome of an aortalgia, or even that of angina pectoris. In the cases associated with aortic insufficiency the valvular lesion is the result of an extension of the syphilitic disease of the vasa vasorum of the aorta to those of the valves. In the cases with aneurysm the weakening of the aortic wall is usually due to a localized development through the media. As in the case of the heart, acute exacerbations of latent aortic lesions occur without known cause. They are also characterized by a polymorphonuclear infiltration, and frequently by localized necrosis in the media. Spirochaetes are easily demonstrated in the aortic lesions by the improved starch-gelatin modification of the Warthin-Starry method. They occur in the perivascular nuclear infiltrations. They are usually not found in large numbers, but in small groups, in the latent lesions. In the acute exacerbations they may be present in very large numbers, and extending into apparently normal aortic tissue, some distance from the area of infiltration.

Para-aortic Vessels.

A favourite site of predilection for the latent lesions of syphilis are the small blood vessels of the para-aortic tissues. Thickening of the arteriole walls occurs, often leading to marked sclerosis or to obliteration of the vessel, while active plasma cell and lymphocyte infiltrations occur around the vessels, particularly around the veins. These lesions may be very slight; in some cases they are the only evidences found of a latent syphilitic infection. Usually, however, the process is continuous with that involving the vasa vasorum of the adventitia. In more severe cases the lymphocyte infiltrations are marked, forming irregular cords of cells following the course of the vessels. They extend along the retroperitoneal vessels, and into the root of the mesentery. Spirochaetes are found in these infiltrations in very small numbers; it is usually more difficult to demonstrate them in these areas than in the infiltrations extending along the aortic vasa vasorum. Very rarely small miliary gummas may develop along the course of these small para-aortic vessels.

Liver.

In both sexes the liver is usually the seat of latent syphilitic lesions. They consist essentially in plasma cell and lymphocyte infiltrations of the periportal tissue, leading eventually to fibrosis and a certain degree of chronic hepatitis. All stages of severity exist, from the mildest to the most severe forms of cirrhosis (hepar lobatum). The frequency of occurrence of a mild grade of atrophic hepatitis in latent syphilitics is very high, as is also that of hepar lobatum. The latter condition, in my experience, is much more frequent in women than in men. The percentage of liver involvement in my material appears to be on the increase, particularly in the cases given a modern treatment with the arsenicals. In fifteen successive necropsies on latent syphilitics performed in my laboratory during the last year there was found a chronic diffuse hepatitis, varying in degree from an early mild form to that of an advanced severe atrophic cirrhosis. The relation of this condition to the treatment rather than to the syphilis remains to be determined. It is probable that the diffuse forms of hepatitis are due to something else than the syphilitic infection, as the syphilitic forms of hepatitis are usually irregular and localized, instead of being diffuse. In the average case the liver presents grossly the picture of brown atrophy and chronic passive congestion, with slight or marked irregularity of the surface. In some cases the small periportal infiltrations occur in livers that otherwise appear perfectly normal. The demonstration of spirochaetes in the hepatic lesions is more difficult and unsatisfactory than in the case of any other organ. They are found usually only in the most active areas of infiltration, and then in small numbers. Throughout the newly formed connective tissue they are not present, or at least cannot be demonstrated.

Pancreas.

Lesions of latent syphilis are common in this organ, in the form of an interstitial pancreatitis not arising from the pancreatic ducts. In the great majority of cases the process is very mild. The interlobular stroma is increased; oedematous, and infiltrated with small collections of plasma cells and lymphocytes. The intralobular stroma is increased, the vessel walls are thickened, and the islands may become fibroid. This lesion may be associated with diabetes, and has been the most common form of pancreatic disease seen in our diabetic material. I believe, therefore, that syphilitic pancreatitis may be one cause of pancreatic insufficiency, although not the only cause. In the severe forms the organ is small, and much firmer than normal; except in cases in which there is marked oedema of the interlobular stroma, in which cases the organ may be larger and softer. Syphilitic pancreatitis is frequently of congenital origin, and may cause pancreatic insufficiency early in life. We have seen two cases of diffuse pancreatic fibrosis in congenital syphilities with enormous numbers of spirochaetes present in all parts of the gland. In the older milder cases the spirochaetes are more difficult of demonstration, because, as a rule, they are few in number, and sharply localized in the active plasma cell infiltrations. They occur singly or in small groups. In a case of very active diffuse interstitial myocarditis occurring in a young man of 24 the pancreas showed large areas of infiltration, associated with the occurrence of aggregations of plasma cells and lymphocytes large enough to be regarded as miliary gummas.

Adrenals.

In the latent syphilitic these organs show almost constantly active infiltrations of plasma cells and lymphocytes varying in size and number from a few small infiltrations

scattered through cortex and medulla, up to diffuse infiltrations of marked degree, with interstitial fibrosis and parenchymatous atrophy, and thickening of the capsule. These lesions are more frequent and more severe in women than in men. While in the average case of latent syphilis these lesions are not severe enough to produce any clinical disturbances referable to the adrenals, yet they may be severe enough to cause marked atrophy and fibrosis of these organs, with a typical picture clinically of Addison's disease. I have seen several such cases, and in my opinion the cases reported in the literature as Addison's disease due to atrophy of the adrenals are probably all of them due to syphilis. There has been an increasing number of such cases reported. Further, I believe that milder degrees of adrenal syphilis may be recognized clinically as a distinct syndrome consisting of low blood pressure, asthenia, irregular patches of pigmentation not marked enough to be regarded as typical of Addison's disease, and accompanied by more or less constant pain in the lumbar region. As has been shown, these cases respond to antisyphilitic treatment, with cure or great improvement in the symptoms. These cases of adrenal syphilis showing a syndrome which might be characterized as sub-Addisonian are probably fairly common among latent syphilities. Spirochaetes are easily demonstrated in the cellular infiltrations, but are usually present in small numbers.

Testis.

The testis of every latent syphilitic shows sooner or later a patchy interstitial orchitis, with atrophy of the germinal epithelium and hyaline fibrosis of the basement membrane of the tubules. The process is usually slow and prolonged over a number of years, but is progressive in character, and ultimately the entire organ may become atrophic and hyaline. It preserves its normal size and consistency, however, in spite of the most marked change. An early loss of spermatogenic function occurs in the majority of those who have had syphilis. Owing to its patchy character and the involvement of individual lobules some sperm may continue to be produced by lobules which are not involved in the process. The interstitial cells usually appear hyperplastic and show a brown pigmentation. In spite of this hyperplasia there is generally a loss or reduction in sexual desire and potency on the part of the latent syphilitic. Spirochaetes are found in the intertubular-cellular infiltrations that are present in the earlier course of the process. They have been found even in the lumen of the tubules and in the hyaline stroma of the basement membrane. They are numerous in the earlier stages, but are extremely difficult to demonstrate in the later atrophic stages.

Ovary.

I have never found a syphilitic lesion in the ovary, or, at least, any lesion that I could convince myself was due to syphilis. Spirochaetes are common in this organ in congenital syphilis, but have never been found in it in acquired syphilis. This organ appears to be immune to the spirochaetes; if not absolutely immune, it at least possesses a very high degree of relative immunity.

Tubes.

The same thing is true of the tubes. They appear to possess a high degree of immunity to the localization or action of the spirochaete. I have never seen any lesions in the tubes of the latent syphilitic woman that I could feel convinced were syphilitic in nature; and I have never found any spirochaetes in the tubes in acquired syphilis. As is true of the ovary, spirochaetes are abundant in the tubes of the syphilitic newborn.

Uterus.

Syphilis of the uterus is by no means rare, both in the primary and in the later stages of the infection. In only a few cases in the latent syphilitic woman have I observed typical syphilitic lesions in the endometrium and extending into the uterine wall, along its smaller blood vessels. There were characteristic perivascular plasma cell and lymphocyte infiltrations, as found elsewhere in the body. Spirochaetes were present in small numbers.

Lymph Nodes.

Latent syphilitic lesions are commonly present in the form of a chronic lymphadenitis which is essentially vascular or perivascular in character. It can usually be recognized histologically only when the process is marked. In such cases spirochaetes are fairly abundant.

Lungs.

Consideration of this organ has been reserved to the last because of the uncertainty of diagnosis of pulmonary latent syphilis. It is true that the latent syphilitic presents a very high percentage of pulmonary fibrosis and chronic passive congestion (induration). Localized patches of fibrosis, usually regarded as chronic broncho-pneumonia, are extremely common in the lungs of latent syphilities, but unless there is a gumma present in association, it is practically impossible to diagnose these fibroses as syphilitic in nature. The infiltrations are less perivascular and show fewer plasma cells than those in other organs, and the fibrosis predominates. The demonstration of the spirochaete is the deciding criterion of pulmonary syphilis, and in the usual necropsy case of latent syphilis this is practically impossible. I have seen not more than fifteen cases in which the presence of pulmonary syphilis was positively proved. The majority of these cases were associated with gummatous lesions; in the others the process was essentially a disease of the pulmonary arteries (cases of Ayerza's disease). Spirochaetes have been demonstrated in the vessel walls of such lungs.

Summary.

It will be seen from the preceding descriptions that the lesion of latent syphilis repeats the essential pathology of the hard chancre and of the secondary and tertiary lesions of the active stage of syphilis, in that it is predominantly vascular and perivascular, and that the infiltrations are derived from the proliferation of cells *in situ*. Each localization of the spirochaete leads to the production of what is essentially a miniature chancre. The presence of plasma cells and lymphocytes in the tissues in the form of localized perivascular infiltrations may be taken as the criterion for the presence of *Spirochæta pallida*. The organisms, therefore, persist in the tissues, producing slight lesions leading eventually to fibrosis and atrophy of the parenchyma. Clinical symptoms will arise only when this atrophy and fibrosis reaches such a degree that functional disturbance results. In the average case in the male this functional inadequacy appears first usually in the cardio-vascular system, and death from latent syphilis is most frequently due to cardiac insufficiency. There are, however, especial organ susceptibilities to the localization of the spirochaete: in one individual the central nervous system, in another the liver, in a third the adrenals, etc., may bear the brunt of the latent infection, so that the clinical picture and the manner of death may vary greatly, according to the organ or tissue chiefly involved.

I have never seen at necropsy a case of perfectly healed syphilis. Search, often prolonged, always reveals active latent lesions in aorta, heart, or other organ. This is as true of cases treated in the modern manner as it is of cases treated with the old mercurial method. If any difference results in the two methods of treatment it would appear to be in the more frequent occurrence of chronic hepatitis in cases treated by the arsenical method. What the treatment accomplishes in either case is the more rapid reduction of the average active case to a stage of latency. There is no evidence pathologically that the case of syphilis ever becomes wholly free from spirochaetes. The latency of the infection may last throughout the individual's life; or at any time exacerbations may take place, and the disease arise above the clinical horizon. What determines these renewals of virulence on the part of the spirochaete, whether it be due to a changed quality on the part of the organism or to changes in the resistance of the body, we do not know. The possibility of such a clinical renewal of activity on the part of the spirochaete is always a possibility hanging over the head of the individual who once acquires this infection. Even if the disease never again produces a clinical outbreak, the relatively immune syphilitic will nevertheless develop various functional

inadequacies as the price of the latency of his infection. These minute local infiltrations of plasma cells and lymphocytes represent the processes of a local tissue immunity. With time this immunity mechanism in itself becomes dangerous to the individual through the functional inadequacies which it may eventually produce. Whether a consistent five-year period of treatment would finally rid the body entirely of spirochaetes I cannot say, for in my material there have been no cases that have been under continuous treatment for that period of time. The fact remains, however, that in syphilitics accorded what has been regarded by the clinician as thoroughly satisfactory treatment, with complete clinical cure, latent lesions of syphilis still present themselves on microscopical examination of the necropsy material derived from such cases.

BILATERAL SPONTANEOUS PNEUMOTHORAX.

REPORT OF A CASE WITH RECOVERY.

BY

D. EVAN BEDFORD, M.D., M.R.C.P.,
ASSISTANT PHYSICIAN TO THE MIDDLESEX HOSPITAL;
AND
H. JOULES, M.D., M.R.C.P.,
MEDICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

(With Special Plate.)

IT is well known that bilateral artificial pneumothorax can safely be employed as a therapeutic measure in suitable cases of bilateral lung disease. Provided that collapse is induced gradually and is carefully controlled, dyspnoea and cyanosis do not occur. Spontaneous pneumothorax, even when unilateral, often provokes severe symptoms owing to the suddenness of the collapse and to the high positive pressure which may develop in the pleural cavity. McLaughlin and Fildes,[1] writing in 1927, state "it is well known that double spontaneous pneumothorax is incompatible with life." We have recently observed the following case of bilateral spontaneous pneumothorax in which, in spite of symptoms of the utmost severity, recovery eventually took place.

A. S., a male aged 19, came to the Middlesex Hospital on March 7th, 1928. He had always enjoyed good health, and had been perfectly well up to the morning of his visit to hospital. On rising at 7 o'clock, he noticed a pain starting beneath the left scapula and working round to the front of the left chest. The pain was described as shooting in character, and gradually increased in severity; it was intensified by any exertion, by deep breathing, or by moving the left arm. Breathlessness started five hours after the onset of pain and gradually became worse. He was seen at hospital at 4 p.m., complaining of severe pain in the chest and of breathlessness.

Examination.

The patient was well developed physically. He appeared to be in the greatest distress; the expression was anxious and the face was pale and somewhat cyanosed. Respiration was laboured, and at each expiration he made a peculiar whistling or whining sound. On attempting to lie flat the face and hands became severely cyanosed. There were exaggerated respiratory movements of the extraordinary muscles of respiration of the neck and upper part of the chest, but the lower part of the chest hardly moved at all, and the intercostal spaces were sucked in during inspiration. The abdominal respiratory movements were excessive. The left side of the chest moved a little better than the right. On percussion there was hyper-resonance over the whole of the chest with absence of cardiac and hepatic dullness; the note over the right base was more drum-like than on the left side. On auscultation hollow blowing breath sounds were heard. The coin apices, but at the bases no breath sounds were just audible at the sound was not elicited. The pulse was regular, rate 90, and of good volume. The blood pressure was 150 mm. systolic. The apex beat was felt in the left nipple line, and the heart sounds were normal.

A tentative diagnosis of right pneumothorax was made, but the absence of displacement of the heart and the unusual chest signs could not be explained, so that it was decided to make an immediate *x*-ray examination. On screening, the heart was normally situated and of normal size, though the vascular pedicle was slightly displaced to the left, and the cardiac pulsation appeared excessive. There was a large pneumothorax on each side of the chest, and both lungs were almost completely collapsed, except for a small area at each apex which remained expanded. There was about half an inch of lung visible surrounding the left border of the heart, and an inch surrounding the right border. With each inspiration there was slight movement of the collapsed lungs. The diaphragm moved well. A radiogram was taken, and is reproduced in the special plate; owing to the urgency of the symptoms a good record was not obtained.

Course.

On arriving in the ward the distress became more severe; the face and arms were almost black, and the pulse became small and rapid. Oxygen was administered by nasal catheter, and the needle of a pneumothorax apparatus was inserted into the fourth right intercostal space, in the anterior axillary line. The intrapleural pressure was so high that fluid was expelled from the manometer, but a pressure of well over 30 cm. of water was certainly present; 550 c.cm. of air were withdrawn slowly, and the intrapleural pressure fell to + 12 – 12 cm. of water. This procedure was attended with most dramatic relief of the distress. Morphine 1/4 grain and strychnine 1/30 grain were then given, and the patient was left receiving continuous intranasal oxygen. The left pneumothorax was not interfered with. During the night he again became severely distressed, and air was allowed to escape by inserting an ordinary serum needle into the right pleural cavity. From this time onwards he remained perfectly comfortable. Slight cyanosis of the lips and cheeks was present for a few days, but there was no distress. Respiration was 24, the pulse 65 to 80, and the temperature remained normal.

During the next fourteen days the physical signs suggested gradual expansion of both lungs, occurring first on the right side. The cardiac and liver dullness remained absent. Signs of fluid were never found, nor was the coin sound ever elicited. The heart was neither palpable nor audible at this period. After two weeks he was allowed up without ill effect. Cough was negligible and sputum scanty in amount, and contained no tubercle bacilli. Physical examination prior to discharge from hospital, on March 28th, 1928, showed the heart to be normally situated; the chest signs suggested that there was still some air in both sides of the chest. An *x*-ray examination on March 23rd, 1928, showed the right lung to be fully expanded and a fairly large pneumothorax still present on the left.

The patient has been kept under observation as an out-patient since his discharge from hospital up to the present time (May, 1929), and no signs or symptoms of any lung lesion have ever been detected. *X*-ray examination on December 12th, 1928, showed both lungs fully expanded and no signs of lung disease.

COMMENT.

Bilateral spontaneous pneumothorax has been previously reported by Benedict,[2] Briggs,[3] Emerson,[4] Hawes,[5] Hazen,[6] Marshank,[7] Meyer,[8] Le Wald,[9] and others; altogether we have been able to find reports of ten cases in the literature. The most frequent underlying cause of spontaneous double pneumothorax is pulmonary tuberculosis, though it may occur in apparently healthy subjects, as in our case. Recovery is uncommon, ensuing in but three of the above, and those that do recover may get a recurrence of pneumothorax.

Le Wald's patient was a healthy male, aged 20, who first had a right pneumothorax, and a week later a large double pneumothorax. Meyer reported a case of bilateral pneumothorax which recurred four times, always during coitus; at necropsy no active tuberculous lesion was found. In Hawes's case, that of a male aged 27, there were recurrent attacks over a period of ten years, involving the right and left sides alternately, recovery eventually taking place.

In our case it is difficult to account for the onset of pneumothorax, which apparently took place during the night and apart from physical exertion. No signs of disease have ever been found, though the patient has now been under close observation for a year, and we may assume that the chest is healthy. The occurrence of bilateral pneumothorax in such a case may have been due to a unilateral pneumothorax with high positive pressure rupturing into the opposite pleural cavity through the mediastinum, as in Le Wald's case, and the fact that severe symptoms were not present until some hours after the onset rather favours this explanation. Another possibility was the existence of a natural communication between the two pleural sacs; this seems unlikely in our case, as the left pneumothorax, which was not aspirated, persisted longer than the right.

With regard to diagnosis, the absence of any displacement of the heart in a case with signs of pneumothorax

and in which there is great distress should suggest a bilateral one. The advisability of aspirating both pleural cavities was considered. Aspiration of the right side, however, gave sufficient relief on both occasions, and it was decided to leave well alone and to avoid all unnecessary interference which might increase the risk of infection. There is no doubt that aspiration saved the patient's life. It seems remarkable that both lungs finally expanded without any complication such as effusion or infection.

We are indebted to Dr. G. E. S. Ward for permission to continue our observation of this case while under his care, and to record it.

NEW ANALYSES OF CARBOHYDRATE FOODS AND THEIR APPLICATION TO DIABETIC DIETS.

BY

R. D. LAWRENCE, M.D., M.R.C.P.,*

AND

R. A. McCANCE, PH.D., M.D.*

(From the Biochemical Department, King's College Hospital.)

ANYONE who has taken the trouble to compare the carbohydrate content of foodstuffs given in different food tables must have been struck by their divergencies and contradictions, often amounting to several hundred per cent. It therefore seemed essential to investigate the subject further if any degree of accuracy in dietetics, and especially diabetic diets, was ever to be obtained. Fresh analyses have therefore been carried out and the results published.[1]

In the past compilers of food tables have largely failed to differentiate between (*a*) starch and the soluble sugars which are completely available as such for metabolism, and (*b*) other carbohydrates such as cellulose, pentosans, inulin, which are certainly not available as carbohydrate and whose exact value in nutrition is doubtful. By our methods of analysis we have separated these two groups, and our final tables show the carbohydrate physiologically available for metabolism. Some of the new figures differ greatly from older ones, as the following comparison shows. The older figures are taken from food tables[2] prepared by Harrison and Lawrence in 1923 from the sources then available. The figures give the percentage of carbohydrate in foods as eaten.

	Percentage Carbohydrate. Old.	New.
Cabbage	2-3	1.0
Celery	3 5	1.0
Lettuce	2.5	0.7
Olives	9.0	0
Rhubarb...	2.5	0.6
Strawberries	9.0	4.4
Tomato	4.0	2.4
Beetroot	7.0	8.0
Potato	20.0	19.2
Bread	50-55	50-55

It will be noticed that great changes appear in most vegetables and fruits, in which much of the total carbohydrate has been found to be "unavailable." On the other hand, the new and old figures agree in foodstuffs rich in the available carbohydrates (sugar and starch), such as beetroot, bread, and potatoes.

Application to Diabetic Diets.

These new analyses explain the specific effect that has been attributed to green vegetables in the treatment of diabetes. Thus when a patient confined himself for a day or two to green vegetables instead of their supposed equivalent of bread or rich carbohydrate food, the glycosuria disappeared. This was because the available carbohydrate was much lower than was supposed.

In practice, therefore, diabetics may always be allowed large amounts of green vegetables, enough to satisfy the most voracious appetite. Moreover, it is quite unnecessary to boil vegetables three times, as was often done in the past, because they contain so little carbohydrate after ordinary domestic methods of cooking. It will be possible in future to make the carbohydrate content of diabetic diets more uniformly accurate, and consequently treatment, and especially experimental therapeutic investigations, may be made more accurate also.

Changes in the Line Ration Diet.

These new food values for carbohydrates have already been incorporated in the line ration diet cards introduced by one of us in 1924,[3] and in the last edition of *The Diabetic Life*.[4] Indeed, some confusion for patients and doctors using the scheme has been unavoidable, as new figures have from time to time been substituted for old as analyses became completed. However, the basis of the scheme is unchanged, and each line still contains 5 grams of carbohydrate, 7½ grams of protein, and 15 grams of fat. The protein and fat food values remain the same, and many of the richer carbohydrate foods, such as bread and potatoes. But practically all the amounts prescribed of green vegetables and many fruits have been increased. The values for such articles as cabbage, spinach, cucumber, and tomatoes have been doubled because the carbohydrate content is about half what we supposed in 1924. A few others, such as lettuce, asparagus, and rhubarb, have been found to contain so little carbohydrate that they have been allowed as "extras," because average helpings contain a negligible amount of carbohydrate.

Naturally the patients are getting more carbohydrate than before, and some have required a few more units of insulin. Depending on the foods chosen by the patient, the increase in carbohydrate now allowed is from 30 to 60 per cent., calculated on old food values. Thus the amount of carbohydrate now allowed in a diet of ten lines (50 grams of carbohydrate) may equal 65 to 80 grams when worked out with previous food values. This increase is probably better for the patient and conforms with the general tendency to increase the carbohydrate in diabetic diets. It has had the effect of reducing the amount of acetone bodies in the urine of patients using the line ration scheme. The ratio of carbohydrate to fat in this scheme was originally intended to be 1 to 3, just high enough to allow complete combustion of fats to proceed. In practice, however, complete combustion was seldom obtained, as Rothera's test was frequently positive in the urine. This was because less carbohydrate was being given than was supposed in theory. The introduction of the new values has corrected this, and the patients' urines are now more consistently free from traces of acetone bodies.

It may be of interest to see how our new figures apply to other schemes of diabetic diets. MacLean's[5] "fifth day" diet contains 42 grams of carbohydrate, but on our new reckoning only about 26 grams. Similarly, some of the sample meals given by Joslin[6] as containing 10 grams of carbohydrate contain only about 5 grams. And working out a ten-line diet (50 grams of carbohydrate) containing much vegetable by the food values given by Joslin (the standard figures used in America) gives a carbohydrate content of 94 grams—admittedly an extreme example. It is interesting to note that Joslin now aims at giving even his severe diabetics 80 to 100 grams of carbohydrate a day—amounts the same as the line ration scheme when the different food values used are considered.

HEALTH PROPAGANDA.

I.—THE ADMINISTRATIVE POINT OF VIEW.*

BY

F. E. WYNNE, M.B., B.Ch., D.P.H.,

MEDICAL OFFICER OF HEALTH FOR THE CITY OF SHEFFIELD;
PROFESSOR OF PUBLIC HEALTH, UNIVERSITY OF SHEFFIELD.

IT seems to me impossible to consider the question of "propaganda" in connexion with health matters as dissociated from education on the same subject. "Propaganda" is in any case a horrible word. Though not born of the war, it is one of the unpleasant things that were popularized as a result of that disastrous episode in modern history. During the war the word "propaganda" came to mean a competitive effort in misleading the public of the particular nation concerned. It is essentially associated with the vulgarity that is an integral part of all successful advertisement. Personally I do not believe that any good thing ever comes out of vulgarity. Having said that, I may say that I have a constitutional objection to what are called, in one of the most offensive items of American slang—also popularized during the war—"stunts."

My belief is that preventive medicine is now winning its way into its true position as the spear-head of medical progress in the future. Everybody agrees that "prevention is better than cure," and there is a great deal of lip service of sanitation and other preventive measures. But the patient and persistent efforts of the members of the public health service and their staffs have not yet achieved—and perhaps never will achieve—the prestige that attaches to the successful physician or surgeon or research worker. This, to some degree, is natural. The work of the public health officer is less individual, and much less dramatic than that of the successful physician or surgeon. This somewhat tends to depreciate the status of the public health administrator in the eyes of the general public in comparison with the status of specialists in other branches of medicine and surgery. This is especially regrettable as, almost more than his colleagues, the medical officer is required to be a "doctor" in the etymological sense of the word.

The primary function of the local sanitary authority is to provide, as far as possible, an environment in which it is possible for all classes of the community to lead a reasonably healthy life. During the present century, however, the activities of local authorities and the expenditure of public funds have been more and more devoted to the personal aspect of public health, and local authorities are now largely concerned in the actual treatment of individuals, through their pre-natal clinics, child-welfare centres, school medical services, tuberculosis services, clinics for venereal diseases, and the administration of the National Health Insurance Act.

All the vast expenditure involved has impressed those responsible with the necessity of instructing the public as to the existence of these services and the proper methods of utilizing them, and in the general principles of hygiene, so that we may maintain the "preventive" principle and lessen the necessity for purely therapeutic measures undertaken for persons who have already become diseased, largely through poverty, ignorance, and faulty environment. Public health propaganda and education has thus become perhaps the latest duty imposed upon local authorities; for the reasons I have given it should be regarded as a basic duty, from the point of view of both improving the public health and promoting economy of public funds. Serious steps in this direction have only been taken quite recently by a minority of local authorities, and those in a somewhat tentative fashion. For instance, it was only during the last financial year that the very progressive health committee of Sheffield allocated a definite portion of its estimates to this purpose. In the meantime much work of this kind has been undertaken by many voluntary organizations, so many that the medical officer of health, who is commissioned by his authority to organize some form of propaganda and education, is utterly bewildered by the number of organizations calling themselves "national councils," and "leagues," and "societies," all competing to advise him and supply him with lectures, demonstrations, exhibitions, and "weeks," devoted to various purposes. The inevitable result is that their competing communications find their way rather quickly to the waste-paper basket. Practically all of these organizations have secured the name of some innocent member of the nobility as president or patron, and a long list of eminent persons as members of their council or committee as the case may be. They all collect subscriptions and have a paid staff, and they tumble over each over in trying to do the same thing. Their multiplication and overlapping has become, in my opinion, almost a public scandal.

A very eminent member of this Association said at a recent meeting that they should all be "scrapped." I do not fully agree with this view. They have a right to exist, and must be given credit for admirable intentions and even a certain amount of achievement; but I am sure they ought to be co-ordinated, and, if I may humbly suggest it, I think this a function which might usefully be carried out by the Minister of Health, who might insist on registration of existing organizations with power to refuse registration to new competitors in this field, and to remove from the register existing organizations found to be obviously redundant. The register might then be reduced from about three hundred to three. The notepaper of one well-known organization of this description contains in its margin a list of affiliated societies which extends all down the page. The number of councils and committees cited, and their subtly different titles, would be comic were it not for the waste of effort and money represented. These organizations also introduce into certain branches of preventive medicine a baneful sentimentality that must tend to bring our work into disrepute. This is typified by the introduction of the word "toddlers" as a description of infants and children between the ages of 1 and 5. The term is now unfortunately officially adopted, although it is not only insulting to childhood, but misleading. It would be more applicable to persons between the age periods 90 to 95, and then it would be an insult to old age.

When the responsible administrative officer has evaded the importunacy of these competing organizations he has to consider very seriously the best methods of instructing the public in the possibilities of avoiding diseases that are the direct outcome of faulty living, and leading the people into the way of health. He has a number of alternatives.

It is a common theory that such instruction should be objective, and appeal mainly to the eye, generally in the form of exhibitions. From that theory evolved the plan of adopting one method of commercial advertisement and devoting a week in the year to "focusing public opinion" on questions of health generally or some special aspect of it, such as the welfare of infants or the extermination of rats. An outcome of this was at one time "baby shows" —the ultimate indignity inflicted on infancy. I was once entrapped into association with a performance of this description. Some 900 mothers brought over 1,000 infants. They were divided into various classes on lines similar to those of the cattle show. There was approximately one prize awarded per 100 exhibitors. The result was about a dozen perspiring but triumphant mothers, and nearly 900 outraged females wounded in their tenderest susceptibilities. Nearly all the babies were made ill, and there was a material rise in the scarlet fever and measles rates of incidence. This was the *reductio ad absurdum* of "propaganda," and thoroughly mischievous. It had no element of educational value.

The other methods available are the promotion of public lectures and instruction in the schools, the distribution of special literature, and judicious use of the public press. Whichever of these methods, be adopted, it is essential that attention these methods, or whatever combination of should be directed to communal health, and that nothing should be done or said to accentuate that morbid absorption in his, or her, own health, on the part of individuals, which is one of the worst vices of our time. The "*malade imaginaire*" was sufficiently rare in the days of Molière to be made a subject of comedy. To-day he is so common as to be a public nuisance, lacking the dignity to become a tragic figure.

* A paper opening a discussion in the Section of Medical Sciences at the Annual Meeting of the British Medical Association, Manchester, 1929.

Briefly, to review the various forms of propaganda enumerated above, the promotion of a "week to focus public attention, etc.," has certainly the advantage of objective appeal, and may be so organized as to have real educational value. On the other hand, it may degenerate into a mere "stunt," stimulating curiosity for a few days, without any lasting effect. It should not be made an annual affair in any locality, as it is certain to become stereotyped and monotonous. It may have great value in small centres of population where public opinion needs stimulation as to the necessity of progressive action towards the advancement of public health. In large centres of population, where administration is already highly organized and progressive, it is unnecessary, and has the grave disadvantage that its organization necessarily falls upon the staff of the public health department and seriously interrupts the routine duties of its officials.

Teaching of hygiene in the schools should be a most valuable means both of propaganda and of education in hygiene. At present I fear it is not. With an overcrowded curriculum, and the necessity of cramming for examinations, the subject is not generally popular among school teachers, directors of education, or those utterly undefined people who arrogate to themselves the title of educationists. In my experience any teaching of hygiene that is given is, with few exceptions, perfunctory and in the wrong hands. In too many cases, especially in the so-called "non-provided" schools, the hygienic conditions in which the children are still compelled to spend a large portion of their childhood are so deplorable that any attempt at "precept" would be merely farcical. In my experience the schools now provided by local authorities are not only sanitary, but provide an environment of dignity which must have an elevating effect on the character, outlook, and ambition of children from the squalid homes of the poorest classes in the community. It is unfortunately nearly always in the schools maintained by the various religious sects in this country that we find conditions that are likely to hasten the departure of children to the next world—doubtless under the best auspices from the point of view of the "denominational" managers.

The promotion of public lectures can be of the utmost value, provided the lectures are given by people with the right experience and the inborn faculty of interesting and really instructing people about subjects in which they are intimately concerned. Public lectures in large halls, given by eminent persons to large audiences, even with the aid of magic lanterns, may be widely attended, but are of doubtful value. On the other hand, intimate conversations on health matters, given to quite small audiences, especially when followed by questions, which develop into a discussion between the lecturer and his audience, can be of real educational value. A number of such lectures have been given in Sheffield under the auspices of the local Insurance Committee actually in the works, and during the employees' own time. They have not only been well attended, but we have evidence that the interest aroused has spread widely among the very classes whom we wish to approach. A great deal of similar and equally successful work is being done under the auspices of the Workers' Education Association and the Miners' Welfare Association.

The distribution of special literature is a process of careful selection, of elimination of propaganda by uninformed or unbalanced faddists, and the encouragement of well-written and sound educational matter. Like every medical officer of health, I have submitted to me an inordinate number of pamphlets, etc., with offers of unlimited supplies for free distribution. I look upon them all with suspicion, and most of them find their way to the wastepaper basket. In common with most of my colleagues, I find the little magazine called *Better Health*, published by the Central Council for Health Education, of real value, and so well edited as to be free from any objectionable features. It is the only publication at present distributed officially by my department, apart from purely local leaflets, etc.

There remains for consideration only the proper use of the press. All medical men know that we have to use great discretion in this matter, and that we are very properly restrained by rules laid down by the General Medical Council. The general health, thanks largely to past propaganda work, has become of such public interest that anything bearing on it is now good "copy" for the press, and consequently welcome. There is accordingly an inducement to medical men to contribute articles dealing with these matters. If such articles are signed, the writer, if in practice, inevitably comes under the suspicion of advertising, which is, and I hope will always continue to be, anathema to the profession in this country. It is, however, open to any medical man to contribute to the press any information which he believes to be of public importance, and reliable, as from "a medical correspondent," and for such contributions he is perfectly entitled to receive any fees usually paid by the journal which publishes his contribution. Personally I believe it to be most important that the public should be kept in touch with the progress of medical science by wise and well-informed contributions to the public press.

In conclusion, I wish to declare my belief that the most important work done in the propagation of knowledge about health matters is that which is being done daily and persistently, without ostentation or advertisement, by our public health departments, their sanitary services, their maternity and child welfare services, their school medical services, tuberculosis services, and other sections of their activities of which the public know little, but from which they derive more benefit than they ever will from any much-advertised "propaganda."

II.—THE PRACTITIONER.*

BY

H. C. JONAS, M.D., B.S.,

SURGEON, BARNSTAPLE AND NORTH DEVON INFIRMARY.

IN any discussion which may prove to be controversial it is a great advantage to find some basis of agreement from which to start. In this case we may well find one in the statement that *health is the most important element in human happiness*. Since the object of propaganda can only be to increase the standard of health, we must, then, agree that the question of its value deserves our sympathetic study and demands our frank and careful scrutiny.

This movement, with the backing of a young and energetic Ministry, has been taken up with enthusiasm by many public-spirited persons. Sections of the press have pushed it in the interests of their readers, or eagerly exploited it in the pursuit of their net sales campaign. The result is that it has attained the rank of a fashion, so that the G.P. (the initials stand for both general practitioner and general public) find it easier to render their unstudied sympathy than to apply the scrutiny either frank or careful.

No one who speaks on this question fails to quote Mr. Lloyd George's phrase: "You cannot run an A1 empire on a C3 population." Having quoted it they consider that there is no necessity to go further, and no one ever inquires into the evidence on which our population was alleged to be C3. If in the interests of careful scrutiny you do inquire, you will find no evidence to disprove, and some to support, the view that it was based on the figures obtained as the result of medical examination of those civilians left when the Conscription Act was passed—that is to say, at a time when Mr. Asquith told us that five million men had already volunteered and had been passed A1. Until someone can disprove this view, and unless figures are produced capable of some sort of comparison with other countries like France and Germany, the phrase has no whit more value for our present discussion than has the exactly parallel statement of fact that "You cannot make butter out of buttermilk."

But apart from all this, there is other evidence that we can judge for ourselves. Both the birth rate and the death rate are falling, therefore the average age of the population must be increasing. It needs no proving that the years per head spent in unproductive old age are also increasing, and it follows that it is more than ever important that the effective years of every life should be as

* Read in a discussion in the Section of Medical Sociology at the Annual Meeting of the British Medical Association, Manchester, 1929.

healthful as possible, in the interests of the nation, apart from all considerations of the happiness of the individual.

In this health campaign every sort of method is adopted. There are lectures, leaflets, posters, films, and, last but not least, powerful articles from the pens of various discarded leaders of medical thought in the columns of certain organs of the press. The most promising sign about all these activities is the stress that is laid on the education of the young. Whether or no the performance keeps faith with that promise is a question which requires our serious consideration. It should always be borne in mind that health is more likely to be attained when it is not the direct object of pursuit. If we wish to instruct the individual, health education is more valuable if it teaches the main conditions of a healthy life, and forms those habits which are likely to attain it.

Everyone here will admit that the Boy Scouts and the Girl Guides are doing the most valuable work possible for those of school age, while the National Association for the Provision of Playing Fields is carrying on the work for the older children and the adolescents. Their success is due to the fact that health is not the direct object of pursuit, but that they do teach those habits which are likely to attain it. It has been claimed that previous health propaganda dots the i's and crosses the t's for all these movements. One can only insist that in so far as they succeed in making the young think of health with a capital H they are doing the very worst thing possible for the furtherance of their ultimate aim.

With regard to the posters here are three questions for the consideration of the meeting:

1. As they are at present do they do any good?
2. Could they be amended so as to do more good?
3. Are they edited with sufficient care?.

The third question I would myself answer with an emphatic *No*.

One poster was put up in at least one child welfare centre depicting in gay and attractive colours a little girl reaching up to get hold of a kettle boiling on an open stove. The audience to be instructed consisted of children under 5 years old. One must admit that is a perfectly sound way of teaching children by bitter experience the maxim "The burnt child shuns the fire"; but surely if the health societies really think it necessary that this lesson has to be learnt by personal experience, it would have been more humane and probably less costly in child life to have instituted during health week, on the lines of the old vaccination stations, a *burning station* where each child was made to touch a red-hot poker. It would at least have been possible to regulate the dosage.

From the extended use that is made of lectures, articles in the press, etc., it is evident that it is not intended to restrict propaganda to the juveniles. No child could be expected to read and enjoy Mr. Bruce Lane's weekly letter in the *Daily Ailment*. Probably more, and not less, care is needed in the editing of these for the advice of adults. Because men and women have more reason to think of their health it is the more incumbent on us to see that our teaching does not fall into the easy but disastrous error of making them think of their ill health. No poster or lecturer ever reminds people to think of their manifold blessings; and yet all doctors in their daily work achieve more than half of their success by engendering in patients a cheery optimism, either because of the doctor's personality, or because, seeing that his doctor does not look worried, the patient decides for himself that all is well.

There are various bodies and societies which devote themselves to certain special aspects of the social health. For instance, the British Council of Social Hygiene, which runs the anti-venereal disease campaign. Its efforts are worthy of all praise, and it does achieve a large measure of success with regard to men; perhaps to a less extent with women. It does produce a certain amount of syphilophobia; but this is a small matter, since the complaint is so promptly cured as soon as advice is sought. In considering the success of this propaganda it must never be forgotten that it has an enormous advantage, in that it advocates early advice, and can point to an almost certain cure free of all expense if its advice is followed.

The position of the cancer leaflets issued by the Ministry of Health is by no means so satisfactory. It would be very valuable if this meeting would discuss thoroughly the advisability of the distribution of these to the public. The leaflets have not the value noted as appertaining to the anti-venereal disease campaign. We cannot point to any certain cure even in the early stages of the disease. We are not able to tell people how to distinguish those symptoms which may arise early enough in the course of the malady to give treatment every possible chance of success with the one exception of uterine haemorrhage after the menopause. On the other hand, we do know that if we circulate these pamphlets we shall cause an enormous number of the laity to be more terrified of cancer than they already are. My own view is definitely against circulation. There is one great disadvantage that a doctor suffers when ill: he knows too much about disease for his own peace of mind; the qualifying mitigation is that his training enables him to appreciate reasons against his worst fears. Why should we hand our disability to the public in an aggravated form, since we can give them part only of the knowledge and none of the training?

It is very difficult to harm the young by propaganda, since they care for none of these things; but with adults the position is vastly different. The particular class of adult which greedily devours everything about health it can get hold of is exactly that type to whom it is most harmful. This group of introspective people is already far too much occupied with the functioning of the various bodily organs. On all of them the effect is bound to be deleterious, to many it will be disastrous. A genuine hypochondriac is a sick man, and as such deserves our respect and care. But does not propaganda tend to produce his pinchbeck imitation the valetudinarian, who is of all men the most miserable, and of all human objects the most useless? So long as health is regarded as a means to a useful life, it is life's greatest boon; once it is made his aim in life, it is man's greatest curse. This danger is peculiarly inherent in the activities of that society which advocates constant regular medical examinations.

The infinitesimal good that might be gained is far outweighed by the enormous harm that is certain to be caused by making people overanxious. Take, for example, their suggestion that all persons should be examined before taking a holiday in order to see what they were fit for. What sort of a holiday would the golfer get after the doctor had told him to wear gumboots on a wet day, the angler who might go out only when the sun had full power, or the Leicestershire man told that he might not jump any fences? Why, the thing is an absurdity.

It is surely unnecessary to say anything on the subject of health weeks. If a man holds that health can only be taught by teaching healthy habits in youth, what can you expect him to say about a scheme which sets aside some hours of one week out of fifty-two for the consideration of the subject? The very idea of a health week is the complete reversal of all his views on health.

Lest you should say that no constructive suggestion has been put forward, may I give you a quotation from *How to Make the Best of Life*, by Dr. Glanville? It contains a truth much neglected at the present time; it is a better motto for a poster than any yet issued by a health society, and it is no bad creed for any man.

"The best way to live well is to work well. Good work is the daily test and safeguard of personal health."

III.—THE PRESS.*

BY

H. A. GWYNNE,

PRESIDENT OF THE INSTITUTE OF JOURNALISTS.

THE press and the medical profession in some respects are opposed to each other, for the former lives and has its being by purveying publicity, while the latter must by the nature of the functions it performs be restrained and discreet. A common ground of agreement between these opposite aims is somewhat difficult to discover, but I am

* Read in a discussion in the Section of Medical Sociology at the Annual Meeting of the British Medical Association, Manchester, 1929.

inclined to think that health propaganda is perhaps the one subject in which the two can co-operate wholeheartedly. We both ardently desire to improve the health of the nation, and we must frankly admit that neither of us can do much in this direction without the help of the other.

I hope this conference will pardon a personal reminiscence, but I relate it only in order to put myself on good terms at the outset with my audience. I am, in a way, a pioneer, for in the year 1913 I published a letter, courageously signed by some of the greatest men of your profession, drawing attention to the grave consequences of the ignorance of the public on the subject of venereal diseases, especially syphilis. It was urged upon me by many eminent doctors and surgeons that such an indictment of our apathy and indifference was necessary in the interests of the nation. I took what little courage was left me by my friends in both hands, published the letter, and supported it warmly with a leading article. The result was that in a short time a matter of great and even vital importance to health was openly discussed and is now no longer confined to the technical columns of the medical press.

It may therefore be taken for granted that the press is only too anxious to march side by side with medicine in the fight for public health. Yet, in spite of this, there are some obstacles to be overcome before we can act together with complete understanding. The press will help in the good work, but it will always want to do so in its own way. The medical profession, bound and tied by strict rules and regulations, would like it done in its way, and there comes the first difficulty. Every newspaper seeks to have an individuality of its own and to carry this individuality right through its pages. For this reason, the concentrated wisdom of all the doctors, if it be distributed to the press generally, will be set aside in favour of the contribution of a lowly general practitioner with a lively pen. Let not this be counted against my profession. I have known of cases where a good-looking doctor with tenuous qualifications has snatched away the woman's portion of the practice of his colleagues in a few months.

Health is a matter of intense interest to everybody, and journalists, having quickly grasped the fact, are naturally eager to provide their readers with the best information they can. In the search for this they often find themselves face to face with the strict rules and regulations of the medical profession. Like many other institutions, such as the Law Society and the Stock Exchange, members are forbidden to advertise, and it has, I believe, been laid down that a signed article in a lay paper is an infraction of this rule. We are thus brought to an impasse. Newspapers require articles at odd times and on odd subjects. They search out the best specialist on the particular subject required, and in nine cases out of ten meet with a ready, not to say eager, response. Then comes the difficulty. It must not be signed by the author—that would bring the wrath of the gods on his head. The article is therefore published as from "a distinguished Harley Street specialist," and all we get for our pains is a series of letters from our readers accusing us of inventing the specialist and writing the article in the office.

Any fair-minded journalist will readily grant that it would not be in the interest of medicine generally that doctors should advertise. It certainly would add to the attraction and revenue of a journal that Dr. X. should use the advertising columns to announce that he would "undertake to make the most melancholy sing in his bath," or that Dr. Y. should say to the world "Don't let them cut you up; let Nature and Dr. Y. put you right without an operation." One's imagination soars at the thought, and, like Clive, we are amazed at our moderation in not starting a press campaign in favour of the abolition of this rule.

Still, there is the problem. We journalists want authoritative information in a hurry, with a name at the top of it, and you of the medical profession would rightly see in that a dangerous innovation which might do infinite harm. It is to be remembered, however, that several eminent doctors do contribute to the press under their own names and no protest appears to have been made by the General Medical Council. Doubtless you might argue that this small band of privileged writers should suffice for the needs of newspapers; but in point of fact they are not numerous enough to fulfil the requirements of the newspaper press to-day. It seems to me that the British Medical Association might well examine this matter and see whether it cannot evolve a solution of the difficulty. As things are at present I am convinced that medicine is losing many great opportunities of teaching the people the great lessons of health, so essential for the well-being of the country.

A cynic once remarked that one of the reasons why a doctor is called in is because the patient has the rare and refreshing opportunity of talking about himself and being heard with attention. Whether that is true or not the fact remains that there is nothing quite so interesting to newspaper readers as discussions on health. Rarely a day passes without a letter being received from a reader asking how best he or she can get fatter or thinner; acquire an appetite or lose some of the craving for food; where to find the best brand of vitamins; whether a whisky-and-soda at bedtime is good for insomnia; or which is the best doctor to consult for persistent halitosis. To our credit be it said that our invariable answer is "Consult a doctor," and in the last case the reply was "Consult any doctor." Such daily experiences are conclusive proofs of the fact that medical matters are, in the language of our craft, "good copy," and therefore it needs no stimulus from outside to quicken our interest in them. However pontifically we may speak to the public on a great variety of subjects, we are quick to realize that it is highly dangerous to pronounce opinions on matters that concern the physical health of our readers. To help us we must turn to your profession, and often in vain.
